## Abstract

We consider the weighted Bartholdi zeta function of a digraph  $D$ , and give a new determinant expression of it. Furthermore, we treat a weighted  $L$ -function of  $D$ , and give a new determinant expression of it. As a corollary, we present determinant expressions for the Bartholdi edge zeta functions of a graph and a digraph.

**Key words:** zeta function, digraph covering,  $L$ -function

## 1 Introduction

Zeta functions of graphs started from zeta functions of regular graphs by Ihara [7]. In [7], he showed that their reciprocals are explicit polynomials. A zeta function of a regular graph  $G$  associated with a unitary representation of the fundamental group of  $G$  was developed by Sunada [12,13]. Hashimoto [6] generalized Ihara's result on the zeta function of a regular graph to an irregular graph, and showed that its reciprocal is again a polynomial by a determinant containing the edge matrix. Bass [2] presented another determinant expression for the Ihara zeta function of an irregular graph by using its adjacency matrix.

Stark and Terras [11] gave an elementary proof of Bass' Theorem, and discussed three different zeta functions of any graph. Furthermore, various proofs of Bass' Theorem were given by Foata and Zeilberger [4], Kotani and Sunada [8].

For two variable zeta function of a graph, Bartholdi [1] defined and gave a determinant expression of the Bartholdi zeta function of a graph. Mizuno and Sato [9] presented a decomposition formula for the Bartholdi zeta function of a regular covering of a graph.

As a digraph version of the Bartholdi zeta function, Choe, Kwak, Park and Sato [3] defined the weighted Bartholdi zeta function of a digraph, and presented its determinant expression.

As a multi-variable zeta function of a graph, Stark and Terras [11] defined the edge zeta function of a graph. Watanabe and Fukumizu [14] presented a determinant expression for the edge zeta function of a graph  $G$  with  $n$  vertices by  $n \times n$  matrices.

In this paper, we present a new determinant expression of the weighted Bartholdi zeta function of a digraph  $D$  by using the method of Watanabe and Fukumizu [14]:

**Main Theorem.**

Let  $D$  be a connected digraph with  $n$  vertices and  $m$  arcs, and let  $\mathbf{W} = \mathbf{W}(D)$  be a weighted matrix of  $D$ . Then the reciprocal of the weighted Bartholdi zeta function of  $D$  is given by

$$\zeta(D, w, u, t)^{-1} = \det(\mathbf{I}_n + (1 - u)t^2\tilde{\mathbf{D}} - t\tilde{\mathbf{A}}_1 - t\tilde{\mathbf{A}}_0) \prod_{i=1}^{m_1} (1 - w(f_i)w(f_i^{-1})(1 - u)^2t^2),$$

where  $\tilde{\mathbf{D}}$ ,  $\tilde{\mathbf{A}}_1$  and  $\tilde{\mathbf{A}}_0$  are defined in Section 3, and  $f_1^{\pm 1}, \dots, f_{m_1}^{\pm 1}$  are symmetric arcs of  $D$ .

Furthermore, we present a new decomposition formula for the weighted Bartholdi zeta function of a group covering of  $D$ , and a new determinant expression for the weighted Bartholdi  $L$ -function of  $D$ .

## 2 Preliminaries

Graphs and digraphs treated here are finite. Let  $G = (V(G), E(G))$  be a connected graph (possibly multiple edges and loops) with the set  $V(G)$  of vertices and the set  $E(G)$  of unoriented edges  $uv$  joining two vertices  $u$  and  $v$ . For  $uv \in E(G)$ , an arc  $(u, v)$  is the oriented edge from  $u$  to  $v$ . Set  $D(G) = \{(u, v), (v, u) \mid uv \in E(G)\}$ . For  $e = (u, v) \in D(G)$ , set  $u = o(e)$  and  $v = t(e)$ . Furthermore, let  $e^{-1} = (v, u)$  be the *inverse* of  $e = (u, v)$ .

A *path*  $P$  of length  $n$  in  $G$  is a sequence  $P = (e_1, \dots, e_n)$  of  $n$  arcs such that  $e_i \in D(G)$ ,  $t(e_i) = o(e_{i+1}) (1 \leq i \leq n - 1)$ , where indices are treated *mod*  $n$ . Set  $|P| = n$ ,  $o(P) = o(e_1)$  and  $t(P) = t(e_n)$ . Also,  $P$  is called an  $(o(P), t(P))$ -*path*. We say that a path  $P = (e_1, \dots, e_n)$  has a *backtracking* or a *bump* at  $t(e_i)$  if  $e_{i+1}^{-1} = e_i$  for some  $i (1 \leq i \leq n - 1)$ . A  $(v, w)$ -path is called a *v-cycle* (or *v-closed path*) if  $v = w$ .

We introduce an equivalence relation between cycles. Two cycles  $C_1 = (e_1, \dots, e_m)$  and  $C_2 = (f_1, \dots, f_m)$  are called *equivalent* if there exists  $k$  such that  $f_j = e_{j+k}$  for all  $j$ . The inverse cycle of  $C$  is in general not equivalent to  $C$ . Let  $[C]$  be the equivalence class which contains a cycle  $C$ . Let  $B^r$  be the cycle obtained by going  $r$  times around a cycle  $B$ . Such a cycle is called a *power* of  $B$ . A cycle  $C$  is *reduced* if  $C$  has no backtracking. Furthermore, a cycle  $C$  is *prime* if it is not a power of a strictly smaller cycle.

The *Ihara zeta function* of a graph  $G$  is a function of  $u \in \mathbf{C}$  with  $|u|$  sufficiently small, defined by

$$\mathbf{Z}(G, t) = \prod_{[C]} (1 - t^{|C|})^{-1},$$

where  $[C]$  runs over all equivalence classes of prime, reduced cycles of  $G$  (see [7]).

Let  $m$  be the number of edges of  $G$ . Furthermore, let two  $m \times m$  matrices  $\mathbf{B} = (\mathbf{B}_{e,f})_{e,f \in A(D)}$  and  $\mathbf{J}_0 = (\mathbf{J}_{e,f})_{e,f \in A(D)}$  be defined as follows:

$$\mathbf{B}_{e,f} = \begin{cases} 1 & \text{if } t(e) = o(f), \\ 0 & \text{otherwise} \end{cases}, \quad \mathbf{J}_{e,f} = \begin{cases} 1 & \text{if } f = e^{-1}, \\ 0 & \text{otherwise.} \end{cases}$$

Then  $\mathbf{B} - \mathbf{J}_0$  is called the *edge matrix* of  $G$ .

**Theorem 1** (Hashimoto; Bass). *Let  $G$  be a connected graph with  $n$  vertices and  $m$  edges. Then the reciprocal of the Ihara zeta function of  $G$  is given by*

$$\mathbf{Z}(G, t)^{-1} = \det(\mathbf{I}_{2m} - t(\mathbf{B} - \mathbf{J}_0)) = (1 - t^2)^{m-n} \det(\mathbf{I} - t\mathbf{A}(G) + t^2(\mathbf{D} - \mathbf{I})),$$

where  $\mathbf{A}(G)$  is the adjacency matrix of  $G$ , and  $\mathbf{D} = (d_{ij})$  is the diagonal matrix with  $d_{ii} = \deg v_i$  where  $V(G) = \{v_1, \dots, v_n\}$ .

Then the *Bartholdi zeta function* of  $G$  is defined by

$$\zeta_G(u, t) = \zeta(G, u, t) = \prod_{[C]} (1 - u^{cbc(C)} t^{|C|})^{-1},$$

where  $[C]$  runs over all equivalence classes of prime cycles of  $G$  (see [1]).

**Theorem 2** (Bartholdi). *Let  $G$  be a connected graph with  $n$  vertices and  $m$  unoriented edges. Then the reciprocal of the Bartholdi zeta function of  $G$  is given by*

$$\begin{aligned} \zeta(G, u, t)^{-1} &= \det(\mathbf{I}_{2m} - t(\mathbf{B} - (1 - u)\mathbf{J}_0)) \\ &= (1 - (1 - u)^2 t^2)^{m-n} \det(\mathbf{I} - t\mathbf{A}(G) + (1 - u)(\mathbf{D} - (1 - u)\mathbf{I})t^2). \end{aligned}$$

In the case of  $u = 0$ , Theorem 2 implies Theorem 1.

We now state the weighted Bartholdi zeta function of a digraph. Let  $D = (V(D), A(D))$  be a connected digraph with the set  $V(D)$  of vertices and the set  $A(D)$  of arcs. Furthermore, let  $D$  have  $n$  vertices  $v_1, \dots, v_n$  and  $m$  arcs. Then we consider an  $n \times n$  matrix  $\mathbf{W} = \mathbf{W}(D) = (w_{ij})_{1 \leq i, j \leq n}$  with  $ij$  entry nonzero complex number  $w_{ij}$  if  $(v_i, v_j) \in A(D)$ , and  $w_{ij} = 0$  otherwise. The matrix  $\mathbf{W} = \mathbf{W}(D)$  is called the *weighted matrix* of  $D$ . Furthermore, let  $w(v_i, v_j) = w_{ij}$ ,  $v_i, v_j \in V(D)$  and  $w(e) = w_{ij}$ ,  $e = (v_i, v_j) \in A(D)$ . For each path  $P = (e_1, \dots, e_r)$  of  $G$ , the *norm*  $w(P)$  of  $P$  is defined as follows:  $w(P) = w(e_1) \cdots w(e_r)$ .

The *cyclic bump count*  $cbc(C)$  of a cycle  $C = (e_1, \dots, e_n)$  of  $G$  is

$$cbc(C) = |\{i = 1, \dots, n \mid e_i = e_{i+1}^{-1}\}|,$$

where  $e_{n+1} = e_1$ . Then the *weighted Bartholdi zeta function* of  $D$  is a function of  $u, t \in \mathbf{C}$  with  $|u|, |t|$  sufficiently small, defined by

$$\zeta(D, w, u, t) = \prod_{[C]} (1 - w(C)u^{bc(C)}t^{|C|})^{-1},$$

where  $[C]$  runs over all equivalence classes of prime cycles of  $D$ .

If  $w = \mathbf{1}$ , i.e.,  $w(v_i, v_j) = 1$  for each  $(v_i, v_j) \in A(D)$ , then the weighted Bartholdi zeta function of  $D$  is the Bartholdi zeta function of  $D$ . If  $D = D_G$  is the symmetric digraph corresponding to a graph  $G$ , and  $w = \mathbf{1}$ , then the weighted Bartholdi zeta function of  $D_G$  is the Bartholdi zeta function of  $G$ . If  $D = D_G$ ,  $w = \mathbf{1}$  and  $u = 0$ , then the weighted Bartholdi zeta function of  $G$  is the Ihara zeta function of  $G$ .

Two  $m \times m$  matrices  $\mathbf{B}_w = (\mathbf{B}_{e,f}^w)_{e,f \in A(D)}$  and  $\mathbf{J}_w = (\mathbf{J}_{e,f}^w)_{e,f \in A(D)}$  are defined as follows:

$$\mathbf{B}_{e,f}^w = \begin{cases} w(e) & \text{if } t(e) = o(f), \\ 0 & \text{otherwise} \end{cases}, \quad \mathbf{J}_{e,f}^w = \begin{cases} w(e) & \text{if } f = e^{-1}, \\ 0 & \text{otherwise.} \end{cases}$$

Furthermore, we define two  $n \times n$  matrices  $\mathbf{W}_1 = \mathbf{W}_1(D) = (a_{uv})$  and  $\mathbf{W}_0$  as follows:

$$a_{uv} = \begin{cases} w(u, v) & \text{if both } (u, v) \text{ and } (v, u) \in A(D), \\ 0 & \text{otherwise} \end{cases}$$

and

$$\mathbf{W}_0 = \mathbf{W}_0(D) = \mathbf{W}(D) - \mathbf{W}_1.$$

Let an  $n \times n$  matrix  $\mathbf{S} = (s_{xy})$  is the diagonal matrix defined by

$$s_{xx} = |\{e \in A(D) \mid o(e) = x, e^{-1} \in A(D)\}|.$$

**Theorem 3** (Choe, Kwak, Park and Sato). *Let  $D$  be a connected digraph, and let  $\mathbf{W} = \mathbf{W}(D)$  be a weighted matrix of  $D$ . Furthermore, let  $m_1 = |\{e \in A(D) \mid e^{-1} \in A(D)\}|/2$ . Then the reciprocal of the weighted Bartholdi zeta function of  $D$  is given by*

$$\zeta(D, w, u, t)^{-1} = \det(\mathbf{I}_m - (\mathbf{B}_w - (1 - u)\mathbf{J}_w)t),$$

where  $n = |V(D)|$  and  $m = |A(D)|$ .

Furthermore, if  $w(e^{-1}) = w(e)^{-1}$  for each  $e \in A(D)$  such that  $e^{-1} \in A(D)$ , then

$$\begin{aligned} \zeta(D, w, u, t)^{-1} &= (1 - (1 - u)^2 t^2)^{m_1 - n} \\ &\times \det(\mathbf{I}_n - t\mathbf{W}_1(D) - (1 - (1 - u)^2 t^2)t\mathbf{W}_0(D) + (1 - u)t^2(\mathbf{S} - (1 - u)\mathbf{I}_n)). \end{aligned}$$

If  $D = D_G$ ,  $w = \mathbf{1}$  and  $u = 0$ , then Theorem 2 implies Theorem 1.

Now, we proceed to the edge zeta function of a graph  $G$  with  $m$  edges. Let  $G$  be a connected graph and  $D(G) = \{e_1, \dots, e_m, e_{m+1}, \dots, e_{2m}\} (e_{m+i} = e_i^{-1} (1 \leq i \leq m))$ . We introduce  $2m$  variables  $z_1, \dots, z_{2m}$ , and set  $g(C) = z_{i_1} \cdots z_{i_k}$  for each cycle  $C =$

### 3 Weighted Bartholdi zeta functions of digraphs

We present a new determinant expression of the weighted Bartholdi zeta function of a digraph.

Let  $D$  be a connected digraph with  $n$  vertices  $v_1, \dots, v_n$  and  $m$  arcs, and  $\mathbf{W} = \mathbf{W}(D)$  a weighted matrix of  $D$ . Then we define two  $n \times n$  matrices  $\tilde{\mathbf{A}}_1 = \tilde{\mathbf{A}}_1(D) = (a_{xy})$  and  $\tilde{\mathbf{A}}_0 = \tilde{\mathbf{A}}_0(D) = (b_{xy})$  as follows:

$$a_{xy} = \begin{cases} w(x, y)/(1 - w(x, y)w(y, x)(1 - u)^2t^2) & \text{if both } (x, y) \text{ and } (y, x) \in A(D), \\ 0 & \text{otherwise} \end{cases}$$

and

$$b_{xy} = \begin{cases} w(x, y) & \text{if } (x, y) \in A(D) \text{ and } (y, x) \notin A(D), \\ 0 & \text{otherwise} \end{cases}$$

Furthermore, an  $n \times n$  matrix  $\tilde{\mathbf{D}} = \tilde{\mathbf{D}}(D) = (d_{xx})$  is the diagonal matrix defined by

$$d_{xx} = \sum_{o(e)=x, e^{-1} \in A(D)} \frac{w(e)w(e^{-1})}{1 - w(e)w(e^{-1})(1 - u)^2t^2}.$$

Let  $\mathbf{M}_1 \oplus \dots \oplus \mathbf{M}_s$  be the block diagonal sum of square matrices  $\mathbf{M}_1, \dots, \mathbf{M}_s$ . A new determinant expression for  $\zeta(D, w, u, t)$  is given as follows:

**Theorem 6.** *Let  $D$  be a connected digraph, and let  $\mathbf{W} = \mathbf{W}(D)$  be a weighted matrix of  $D$ . Then the reciprocal of the weighted Bartholdi zeta function of  $D$  is given by*

$$\zeta(D, w, u, t)^{-1} = \det(\mathbf{I}_n + (1 - u)t^2\tilde{\mathbf{D}} - t\tilde{\mathbf{A}}_1 - t\tilde{\mathbf{A}}_0) \prod_{i=1}^{m_1} (1 - w(f_i)w(f_i^{-1})(1 - u)^2t^2),$$

where  $n = |V(D)|$ ,  $m = |A(D)|$  and  $f_1^{\pm 1}, \dots, f_{m_1}^{\pm 1}$  are symmetric arcs of  $D$ .

**Proof.** Let  $V(D) = \{v_1, \dots, v_n\}$  and, let  $A(D) = \{e_1, \dots, e_{m_0}, f_1, \dots, f_{m_1}, f_1^{-1}, \dots, f_{m_1}^{-1}\}$  such that  $e_i^{-1} \notin A(D) (1 \leq i \leq m_0)$ . Note that  $m = m_0 + 2m_1$ .

Arrange arcs of  $D$  as follows:

$$e_1, \dots, e_{m_0}, f_1, f_1^{-1}, \dots, f_{m_1}, f_{m_1}^{-1}.$$

Let

$$\mathbf{U} = \begin{bmatrix} w(e_1) & & & & & 0 \\ & \ddots & & & & \\ & & w(e_{m_0}) & & & \\ & & & w(f_1) & & \\ & & & & w(f_1^{-1}) & \\ 0 & & & & & \ddots \end{bmatrix}.$$

Then we have

$$\mathbf{UB} = \mathbf{B}_w \text{ and } \mathbf{UJ}_0 = \mathbf{J}_w.$$

Thus,

$$\mathbf{B}_w - (1 - u)\mathbf{J}_w = \mathbf{U}(\mathbf{B} - (1 - u)\mathbf{J}_0).$$

By Theorem 2, it follows that

$$\zeta(D, w, u, t)^{-1} = \det(\mathbf{I}_m - t\mathbf{U}(\mathbf{B} - (1 - u)\mathbf{J}_0)).$$

Now, let  $\mathbf{K} = (\mathbf{K}_{ev})_{e \in A(D); v \in V(D)}$  be the  $m \times n$  matrix defined as follows:

$$\mathbf{K}_{ev} := \begin{cases} 1 & \text{if } o(e) = v, \\ 0 & \text{otherwise.} \end{cases}$$

Furthermore, we define the  $m \times n$  matrix  $\mathbf{L} = (\mathbf{L}_{ev})_{e \in A(D); v \in V(D)}$  as follows:

$$\mathbf{L}_{ev} := \begin{cases} 1 & \text{if } t(e) = v, \\ 0 & \text{otherwise.} \end{cases}$$

Then we have

$$\mathbf{L}^t \mathbf{K} = \mathbf{B}.$$

Thus,

$$\begin{aligned} & \det(\mathbf{I}_m - t\mathbf{U}(\mathbf{B} - (1 - u)\mathbf{J}_0)) \\ &= \det(\mathbf{I}_m - t\mathbf{U}(\mathbf{L}^t \mathbf{K} - (1 - u)\mathbf{J}_0)) = \det(\mathbf{I}_m - t\mathbf{U}\mathbf{L}^t \mathbf{K} + (1 - u)t\mathbf{U}\mathbf{J}_0). \end{aligned}$$

But, we have

$$\mathbf{I}_m + (1 - u)t\mathbf{U}\mathbf{J}_0 = \mathbf{I}_{m_0} \oplus \left( \bigoplus_{j=1}^{m_1} \begin{bmatrix} 1 & (1 - u)tw(f_j) \\ (1 - u)tw(f_j^{-1}) & 1 \end{bmatrix} \right). \quad (1)$$

Since  $|u|, |t|$  are sufficiently small, we have

$$\det\left( \begin{bmatrix} 1 & (1 - u)tw(f_j) \\ (1 - u)tw(f_j^{-1}) & 1 \end{bmatrix} \right) = 1 - (1 - u)^2 t^2 w(f_j)w(f_j^{-1}) \neq 0 \quad (1 \leq j \leq m_1).$$

Thus,  $\mathbf{I}_m + (1 - u)t\mathbf{U}\mathbf{J}_0$  is invertible. Therefore,

$$\begin{aligned} & \det(\mathbf{I}_m - t\mathbf{U}(\mathbf{B} - (1 - u)\mathbf{J}_0)) \\ &= \det(\mathbf{I}_m - t\mathbf{U}\mathbf{L}^t \mathbf{K}(\mathbf{I}_m + (1 - u)t\mathbf{U}\mathbf{J}_0)^{-1}) \det(\mathbf{I}_m + (1 - u)t\mathbf{U}\mathbf{J}_0). \end{aligned}$$

But, if  $\mathbf{A}$  and  $\mathbf{B}$  are a  $m \times n$  and  $n \times m$  matrices, respectively, then we have

$$\det(\mathbf{I}_m - \mathbf{A}\mathbf{B}) = \det(\mathbf{I}_n - \mathbf{B}\mathbf{A}). \quad (2)$$

Thus, we have

$$\begin{aligned} & \det(\mathbf{I}_m - t\mathbf{U}(\mathbf{B} - (1 - u)\mathbf{J}_0)) \\ &= \det(\mathbf{I}_n - t^t \mathbf{K}(\mathbf{I}_m + (1 - u)t\mathbf{U}\mathbf{J}_0)^{-1} \mathbf{U}\mathbf{L}) \det(\mathbf{I}_m + (1 - u)t\mathbf{U}\mathbf{J}_0). \end{aligned}$$

Next, we have

$$\det(\mathbf{I}_m + (1-u)t\mathbf{UJ}_0) = \prod_{i=1}^{m_1} (1 - w(f_i)w(f_i^{-1})(1-u)^2t^2).$$

Furthermore, the  $m \times n$  matrix  $\mathbf{UL} = (c_{ev})_{e \in A(D); v \in V(D)}$  is given as follows:

$$c_{ev} := \begin{cases} w(e) & \text{if } t(e) = v, \\ 0 & \text{otherwise.} \end{cases}$$

But, we have

$$(\mathbf{I}_m + (1-u)t\mathbf{UJ}_0)^{-1} = \mathbf{I}_{m_0} \oplus \left( \bigoplus_{j=1}^{m_1} \begin{bmatrix} 1/x_j & -(1-u)tw(f_j)/x_j \\ -(1-u)tw(f_j^{-1})/x_j & 1/x_j \end{bmatrix} \right),$$

where  $x_i = 1 - w(f_i)w(f_i^{-1})(1-u)^2t^2$  ( $1 \leq i \leq m_1$ ).

Now, for a symmetric arc  $(x, y) \in A(D)$ ,

$$({}^t\mathbf{K}(\mathbf{I}_m + (1-u)t\mathbf{UJ}_0)^{-1}\mathbf{UL})_{xy} = w(x, y)/(1 - w(x, y)w(y, x)(1-u)^2t^2).$$

For a nonsymmetric arc  $(x, y) \in A(D)$ ,

$$({}^t\mathbf{K}(\mathbf{I}_m + (1-u)t\mathbf{UJ}_0)^{-1}\mathbf{UL})_{xy} = w(x, y).$$

Furthermore, if  $x = y$ , then

$$({}^t\mathbf{K}(\mathbf{I}_m + (1-u)t\mathbf{UJ}_0)^{-1}\mathbf{UL})_{xx} = - \sum_{o(e)=x, e^{-1} \in A(D)} \frac{(1-u)tw(e)w(e^{-1})}{1 - w(e)w(e^{-1})(1-u)^2t^2}.$$

Thus,

$$\det(\mathbf{I}_n - t {}^t\mathbf{K}(\mathbf{I}_m + (1-u)t\mathbf{UJ}_0)^{-1}\mathbf{UL}) = \det(\mathbf{I}_n + (1-u)t^2\tilde{\mathbf{D}} - t\tilde{\mathbf{A}}_1 - t\tilde{\mathbf{A}}_0).$$

Therefore, it follows that

$$\zeta(D, w, u, t)^{-1} = \det(\mathbf{I}_n + (1-u)t^2\tilde{\mathbf{D}} - t\tilde{\mathbf{A}}_1 - t\tilde{\mathbf{A}}_0) \prod_{i=1}^{m_1} (1 - w(f_i)w(f_i^{-1})(1-u)^2t^2).$$

□

By Theorem 5, we obtain the second identity of Theorem 2.

**Corollary 1** (Choe, Kwak, Park and Sato). *Let  $D$  be a connected digraph, and let  $\mathbf{W} = \mathbf{W}(D)$  be a weighted matrix of  $D$ . Furthermore, assume that  $w(e^{-1}) = w(e)^{-1}$  for each  $e \in A(D)$  such that  $e^{-1} \in A(D)$ . Then the reciprocal of the weighted Bartholdi zeta function of  $D$  is given by*

$$\zeta(D, w, u, t)^{-1} = (1 - (1-u)^2t^2)^{m_1-n}$$

$$\times \det(\mathbf{I}_n - t\mathbf{W}_1(D) - (1 - (1-u)^2t^2)t\mathbf{W}_0(D) + (1-u)t^2(\mathbf{S} - (1-u)\mathbf{I}_n)).$$

where  $n = |V(D)|$  and  $m = |A(D)|$ .

**Proof.** Since  $w(e^{-1}) = w(e)^{-1}$  for each symmetric arc  $e \in A(D)$ , we have  $w(e^{-1})w(e)^{-1} = 1$ . Then we have

$$\tilde{\mathbf{D}} = \frac{1}{1 - (1 - u)^2 t^2} \mathbf{S}, \quad \tilde{\mathbf{A}}_1 = \frac{1}{1 - (1 - u)^2 t^2} \mathbf{W}_1(D).$$

Furthermore,  $\tilde{\mathbf{A}}_0 = \mathbf{W}_0(D)$ . Thus,

$$\begin{aligned} \zeta(D, w, u, t)^{-1} &= (1 - (1 - u)^2 t^2)^{m_1} \det \left( \mathbf{I}_n - t/(1 - (1 - u)^2 t^2) \mathbf{W}_1(D) \right. \\ &\quad \left. - t \mathbf{W}_0(D) + (1 - u) t^2 / (1 - (1 - u)^2 t^2) \mathbf{S} \right) \\ &= (1 - (1 - u)^2 t^2)^{m_1 - n} \det \left( \mathbf{I}_n - t \mathbf{W}_1(D) - (1 - (1 - u)^2 t^2) t \mathbf{W}_0(D) \right. \\ &\quad \left. + (1 - u) t^2 (\mathbf{S} - (1 - u) \mathbf{I}_n) \right). \end{aligned}$$

□

## 4 Weighted Bartholdi zeta functions of group coverings of digraphs

We can generalize the notion of a  $\Gamma$ -covering of a graph to a simple digraph. Let  $D$  be a connected digraph and  $\Gamma$  a finite group. Then a mapping  $\alpha : A(D) \rightarrow \Gamma$  is called a *pseudo ordinary voltage assignment* if  $\alpha(v, u) = \alpha(u, v)^{-1}$  for each  $(u, v) \in A(D)$  such that  $(v, u) \in A(D)$ . The pair  $(D, \alpha)$  is called an *ordinary voltage digraph*. The *derived digraph*  $D^\alpha$  of the ordinary voltage digraph  $(D, \alpha)$  is defined as follows:  $V(D^\alpha) = V(D) \times \Gamma$  and  $((u, h), (v, k)) \in A(D^\alpha)$  if and only if  $(u, v) \in A(D)$  and  $k = h\alpha(u, v)$ . The digraph  $D^\alpha$  is called a  $\Gamma$ -*covering* of  $D$ . Note that a  $\Gamma$ -covering of the symmetric digraph corresponding to a graph  $G$  is a  $\Gamma$ -covering of  $G$  (see [5]).

Let  $D$  be a connected digraph,  $\Gamma$  a finite group and  $\alpha : A(D) \rightarrow \Gamma$  a pseudo ordinary voltage assignment. In the  $\Gamma$ -covering  $D^\alpha$ , set  $v_g = (v, g)$  and  $e_g = (e, g)$ , where  $v \in V(D), e \in A(D), g \in \Gamma$ . For  $e = (u, v) \in A(D)$ , the arc  $e_g$  emanates from  $u_g$  and terminates at  $v_{g\alpha(e)}$ .

Let  $\mathbf{W} = \mathbf{W}(D)$  be a weighted matrix of  $D$ . Then we define the *weighted matrix*  $\tilde{\mathbf{W}} = \mathbf{W}(D^\alpha) = (\tilde{w}(u_g, v_h))$  of  $D^\alpha$  derived from  $\mathbf{W}$  as follows:

$$\tilde{w}(u_g, v_h) := \begin{cases} w(u, v) & \text{if } (u, v) \in A(D) \text{ and } h = g\alpha(u, v), \\ 0 & \text{otherwise.} \end{cases}$$

If  $\mathbf{M}_1 = \mathbf{M}_2 = \dots = \mathbf{M}_s = \mathbf{M}$ , then we write  $s \circ \mathbf{M} = \mathbf{M}_1 \oplus \dots \oplus \mathbf{M}_s$ . The *Kronecker product*  $\mathbf{A} \otimes \mathbf{B}$  of matrices  $\mathbf{A}$  and  $\mathbf{B}$  is considered as the matrix  $\mathbf{A}$  having the element  $a_{ij}$  replaced by the matrix  $a_{ij}\mathbf{B}$ .

**Theorem 7.** *Let  $D$  be a connected digraph with  $n$  vertices and  $m$  arcs,  $\Gamma$  a finite group,  $\alpha : A(D) \rightarrow \Gamma$  a pseudo ordinary voltage assignment and  $\mathbf{W} = \mathbf{W}(D)$  a weighted*

matrix of  $D$ . Set  $m_1 = |\{e \in A(D) \mid e^{-1} \in A(D)\}| / 2$  and  $|\Gamma| = r$ . Furthermore, let  $\rho_1 = 1, \rho_2, \dots, \rho_k$  be the irreducible representations of  $\Gamma$ , and  $d_i$  the degree of  $\rho_i$  for each  $i$ , where  $d_1 = 1$ . For  $g \in \Gamma$ , the matrix  $\mathbf{A}_{1,g} = (a_{xy}^{(g)})$  is defined as follows:

$$a_{xy}^{(g)} := \begin{cases} w(x,y)/(1-w(x,y)w(y,x)(1-u)^2t^2) & \text{if } (x,y), (y,x) \in A(D) \text{ and } \alpha(x,y) = g, \\ 0 & \text{otherwise.} \end{cases}$$

Furthermore, the matrix  $\mathbf{A}_{0,g} = (b_{xy}^{(g)})$  is defined as follows:

$$b_{xy}^{(g)} := \begin{cases} w(x,y) & \text{if } (x,y) \in A(D), (y,x) \notin A(D) \text{ and } \alpha(x,y) = g, \\ 0 & \text{otherwise.} \end{cases}$$

Suppose that the  $\Gamma$ -covering  $D^\alpha$  of  $D$  is connected. Then the reciprocal of the weighted Bartholdi zeta function of  $D^\alpha$  is

$$\zeta(D^\alpha, \tilde{w}, u, t)^{-1} = \prod_{i=1}^{m_1} (1 - w(f_i)w(f_i^{-1})(1-u)^2t^2)^r \\ \times \prod_{i=1}^k \left\{ \det(\mathbf{I}_{nd_i} - t \sum_{h \in \Gamma} \rho_i(h) \otimes \mathbf{A}_{1,h} - t \sum_{h \in \Gamma} \rho_i(h) \otimes \mathbf{A}_{0,h} + (1-u)t^2(\mathbf{I}_{d_i} \otimes \tilde{\mathbf{D}}(D))) \right\}^{d_i},$$

where  $f_1^{\pm 1}, \dots, f_{m_1}^{\pm 1}$  are symmetric arcs of  $D$ .

**Proof .** Let  $V(D) = \{v_1, \dots, v_n\}$  and  $\Gamma = \{1 = g_1, g_2, \dots, g_r\}$ . Arrange vertices of  $D^\alpha$  in  $n$  blocks:  $(v_1, 1), \dots, (v_n, 1); (v_1, g_2), \dots, (v_n, g_2); \dots; (v_1, g_r), \dots, (v_n, g_r)$ . We consider the three matrices  $\tilde{\mathbf{A}}_1(D^\alpha)$ ,  $\tilde{\mathbf{W}}_0(D^\alpha)$  and  $\tilde{\mathbf{D}}(D^\alpha)$  under this order. By Theorem 5, we have

$$\zeta(D^\alpha, \tilde{w}, u, t)^{-1} = \det(\mathbf{I}_{\nu m} - t\tilde{\mathbf{A}}_1(D^\alpha) - t\tilde{\mathbf{A}}_0(D^\alpha) + (1-u)t^2\tilde{\mathbf{D}}(D^\alpha)) \\ \cdot \prod_{i=1}^{m_1} (1 - w(f_i)w(f_i^{-1})(1-u)^2t^2)^r.$$

For  $h \in \Gamma$ , the matrix  $\mathbf{P}_h = (p_{ij}^{(h)})$  is defined as follows:

$$p_{ij}^{(h)} = \begin{cases} 1 & \text{if } g_i h = g_j, \\ 0 & \text{otherwise.} \end{cases}$$

Suppose that  $p_{ij}^{(h)} = 1$ , i.e.,  $g_j = g_i h$ . Then  $((u, g_i), (v, g_j)) \in A(D^\alpha)$  if and only if  $(u, v) \in A(D)$  and  $g_j = g_i \alpha(u, v)$ , i.e.,  $\alpha(u, v) = g_i^{-1} g_j = g_i^{-1} g_i h = h$ . Thus we have

$$\tilde{\mathbf{A}}_0(D^\alpha) = \sum_{h \in \Gamma} \mathbf{P}_h \otimes \mathbf{A}_{0,h} \text{ and } \tilde{\mathbf{A}}_1(D^\alpha) = \sum_{h \in \Gamma} \mathbf{P}_h \otimes \mathbf{A}_{1,h}.$$

Let  $\rho$  be the right regular representation of  $\Gamma$ . Furthermore, let  $\rho_1 = 1, \rho_2, \dots, \rho_k$  be the irreducible representations of  $\Gamma$ , and  $d_i$  the degree of  $\rho_i$  for each  $i$ , where  $d_1 = 1$ . Then

we have  $\rho(h) = \mathbf{P}_h$  for  $h \in \Gamma$ . Furthermore, there exists a nonsingular matrix  $\mathbf{P}$  such that  $\mathbf{P}^{-1}\rho(h)\mathbf{P} = (1) \oplus d_2 \circ \rho_2(h) \oplus \cdots \oplus d_k \circ \rho_k(h)$  for each  $h \in \Gamma$  (see [10]). Putting  $\mathbf{B} = (\mathbf{P}^{-1} \otimes \mathbf{I}_n)(\tilde{\mathbf{A}}_1(D^\alpha) + \tilde{\mathbf{A}}_0(D^\alpha))(\mathbf{P} \otimes \mathbf{I}_n)$ , we have

$$\mathbf{B} = \sum_{h \in \Gamma} \{(1) \oplus d_2 \circ \rho_2(h) \oplus \cdots \oplus d_k \circ \rho_k(h)\} \otimes (\mathbf{A}_{1,h} + \mathbf{A}_{0,h}).$$

Note that  $\tilde{\mathbf{A}}_i(D) = \sum_{h \in \Gamma} \mathbf{A}_{i,h}$  ( $i = 0, 1$ ) and  $1 + d_2^2 + \cdots + d_k^2 = r$ . Therefore it follows that

$$\zeta(D^\alpha, \tilde{w}, u, t)^{-1} = \prod_{j=1}^{m_1} (1 - w(f_j)w(f_j^{-1})(1 - u)^2 t^2)^r$$

$$\times \prod_{i=1}^k \det(\mathbf{I}_{nd_i} - t \sum_{h \in \Gamma} \rho_i(h) \otimes \mathbf{A}_{1,h} - t \sum_{h \in \Gamma} \rho_i(h) \otimes \mathbf{A}_{0,h} + (1 - u)t^2(\mathbf{I}_{d_i} \otimes \tilde{\mathbf{D}}(D)))^{d_i}.$$

□

## 5 L-functions of digraphs

Let  $D$  be a connected digraph with  $m$  arcs,  $\Gamma$  a finite group,  $\alpha : A(D) \rightarrow \Gamma$  a pseudo ordinary voltage assignment and  $\mathbf{W} = \mathbf{W}(D)$  a weighted matrix of  $D$ . For each path  $P = (e_1, \dots, e_l)$  of  $D$ , set  $\alpha(P) = \alpha(e_1) \cdots \alpha(e_l)$  and  $w(P) = w(e_1) \cdots w(e_l)$ . Furthermore, let  $\rho$  be a representation of  $\Gamma$  and  $d$  its degree.

The *weighted Bartholdi L-function* of  $D$  associated with  $\rho$  and  $\alpha$  is defined by

$$\zeta_D(w, u, t, \rho, \alpha) = \prod_{[C]} \det(\mathbf{I}_d - w(C)\rho(\alpha(C))u^{bc(C)}t^{|C|})^{-1},$$

where  $[C]$  runs over all equivalence classes of prime cycles of  $D$ .

Two  $md \times md$  matrices  $\mathbf{B}_w^\rho = (\mathbf{B}_{e,f})_{e,f \in A(D)}$  and  $\mathbf{J}_w^\rho = (\mathbf{J}_{e,f})_{e,f \in A(D)}$  are defined as follows:

$$\mathbf{B}_{e,f} = \begin{cases} w(e)\rho(\alpha(e)) & \text{if } t(e) = o(f), \\ \mathbf{0}_d & \text{otherwise} \end{cases}, \quad \mathbf{J}_{e,f} = \begin{cases} w(e)\rho(\alpha(e)) & \text{if } f = e^{-1}, \\ \mathbf{0}_d & \text{otherwise.} \end{cases}$$

A determinant expression for the weighted Bartholdi  $L$ -function of  $D$  associated with  $\rho$  and  $\alpha$  was given by Choe, Kwak, Park and Sato [3]. Let  $1 \leq i, j \leq n$ . Then the  $(i, j)$ -block  $\mathbf{F}_{ij}$  of a  $dn \times dn$  matrix  $\mathbf{F}$  is the submatrix of  $\mathbf{F}$  consisting of  $d(i-1) + 1, \dots, di$  rows and  $d(j-1) + 1, \dots, dj$  columns.

**Theorem 8** (Choe, Kwak, Park and Sato). *Let  $D$  be a connected digraph with  $m$  arcs,  $\Gamma$  a finite group,  $\alpha : A(D) \rightarrow \Gamma$  a pseudo ordinary voltage assignment and  $\mathbf{W} = \mathbf{W}(D)$  a weighted matrix of  $D$ . Furthermore, let  $\rho$  be a representation of  $\Gamma$ , and  $d$  the degree of  $\rho$ . Then the reciprocal of the weighted Bartholdi  $L$ -function of  $D$  associated with  $\rho$  and  $\alpha$  is*

$$\zeta_D(w, u, t, \rho, \alpha)^{-1} = \det(\mathbf{I}_{md} - (\mathbf{B}_w^\rho - (1 - u)\mathbf{J}_w^\rho)t).$$

Furthermore, we define the  $md \times nd$  matrix  $\mathbf{L} = (\mathbf{L}_{ev})_{e \in A(D); v \in V(D)}$  as follows:

$$\mathbf{L}_{ev} := \begin{cases} \rho(\alpha(e)) & \text{if } t(e) = v, \\ \mathbf{0}_d & \text{otherwise.} \end{cases}$$

Set  $\mathbf{U}_d = \mathbf{U} \otimes \mathbf{I}_d$ . Then we have

$$\mathbf{L}^t \mathbf{K} = \mathbf{B}_\rho.$$

Thus,

$$\begin{aligned} & \det(\mathbf{I}_{md} - t\mathbf{U}_d(\mathbf{B}_\rho - (1-u)\mathbf{J}_\rho)) \\ &= \det(\mathbf{I}_{md} - t\mathbf{U}_d(\mathbf{L}^t \mathbf{K} - (1-u)\mathbf{J}_\rho)) = \det(\mathbf{I}_{md} - t\mathbf{U}_d \mathbf{L}^t \mathbf{K} + (1-u)t\mathbf{U}_d \mathbf{J}_\rho). \end{aligned}$$

But, we have

$$\begin{aligned} & \mathbf{I}_{md} + (1-u)t\mathbf{U}_d \mathbf{J}_\rho \\ &= \mathbf{I}_{m_0d} \oplus \left( \bigoplus_{j=1}^{m_1} \begin{bmatrix} \mathbf{I}_d & (1-u)tw(f_j)\rho(\alpha(f_j)) \\ (1-u)tw(f_j^{-1})\rho(\alpha(f_j^{-1})) & \mathbf{I}_d \end{bmatrix} \right). \end{aligned} \quad (3)$$

Since  $|u|, |t|$  are sufficiently small, we have

$$\begin{aligned} & \det \left( \begin{bmatrix} \mathbf{I}_d & (1-u)tw(f_j)\rho(\alpha(f_j)) \\ (1-u)tw(f_j^{-1})\rho(\alpha(f_j^{-1})) & \mathbf{I}_d \end{bmatrix} \right) \\ &= (1 - (1-u)^2 t^2 w(f_j)w(f_j^{-1}))^d \neq 0 \quad (1 \leq j \leq m_1). \end{aligned}$$

Thus,  $\mathbf{I}_{md} + (1-u)t\mathbf{U}_d \mathbf{J}_\rho$  is invertible. Therefore,

$$\begin{aligned} & \det(\mathbf{I}_{md} - t\mathbf{U}_d(\mathbf{B}_\rho - (1-u)\mathbf{J}_\rho)) \\ &= \det(\mathbf{I}_{md} - t\mathbf{U}_d \mathbf{L}^t \mathbf{K} (\mathbf{I}_{md} + (1-u)t\mathbf{U}_d \mathbf{J}_\rho)^{-1}) \det(\mathbf{I}_{md} + (1-u)t\mathbf{U}_d \mathbf{J}_\rho). \end{aligned}$$

By (2), we have

$$\begin{aligned} & \det(\mathbf{I}_{md} - t\mathbf{U}_d(\mathbf{B}_\rho - (1-u)\mathbf{J}_\rho)) \\ &= \det(\mathbf{I}_{nd} - t \mathbf{K} (\mathbf{I}_{nd} + (1-u)t\mathbf{U}_d \mathbf{J}_\rho)^{-1} \mathbf{U}_d \mathbf{L}) \det(\mathbf{I}_{md} + (1-u)t\mathbf{U}_d \mathbf{J}_\rho). \end{aligned}$$

Next, we have

$$\det(\mathbf{I}_{md} + (1-u)t\mathbf{U}_d \mathbf{J}_\rho) = \prod_{i=1}^{m_1} (1 - w(f_i)w(f_i^{-1})(1-u)^2 t^2)^d.$$

Furthermore, the  $md \times nd$  matrix  $\mathbf{U}_d \mathbf{L} = (c_{ev})_{e \in A(D); v \in V(D)}$  is given as follows:

$$c_{ev} := \begin{cases} w(e)\rho(\alpha(e)) & \text{if } t(e) = v, \\ 0 & \text{otherwise.} \end{cases}$$

But, we have

$$\begin{aligned}
& (\mathbf{I}_{md} + (1-u)t\mathbf{U}_d\mathbf{J}_\rho)^{-1} \\
&= \mathbf{I}_{m_0d} \oplus \left( \bigoplus_{j=1}^{m_1} \begin{bmatrix} 1/x_j\mathbf{I}_d & -(1-u)tw(f_j)/x_j\rho(\alpha(f_j)) \\ -(1-u)tw(f_j^{-1})/x_j\rho(\alpha(f_j^{-1})) & 1/x_j\mathbf{I}_d \end{bmatrix} \right).
\end{aligned}$$

where  $x_i = 1 - w(f_i)w(f_i^{-1})(1-u)^2t^2$  ( $1 \leq i \leq m_1$ ).

But, for a symmetric arc  $(x, y) \in A(D)$ ,

$$({}^t\mathbf{K}(\mathbf{I}_{md} + (1-u)t\mathbf{U}_d\mathbf{J}_\rho)^{-1}\mathbf{U}_d\mathbf{L})_{xy} = w(x, y)/(1 - w(x, y)w(y, x)(1-u)^2t^2)\rho(\alpha(x, y)).$$

For a nonsymmetric arc  $(x, y) \in A(D)$ ,

$$({}^t\mathbf{K}(\mathbf{I}_{md} + (1-u)t\mathbf{U}_d\mathbf{J}_\rho)^{-1}\mathbf{U}_d\mathbf{L})_{xy} = w(x, y)\rho(\alpha(x, y)).$$

Furthermore, if  $x = y$ , then

$$({}^t\mathbf{K}(\mathbf{I}_{md} + (1-u)t\mathbf{U}_d\mathbf{J}_\rho)^{-1}\mathbf{U}_d\mathbf{L})_{xx} = - \sum_{o(e)=x, e^{-1} \in A(D)} \frac{(1-u)tw(e)w(e^{-1})}{1 - w(e)w(e^{-1})(1-u)^2t^2} \mathbf{I}_d.$$

Thus,

$$\begin{aligned}
& \det(\mathbf{I}_{nd} - t {}^t\mathbf{K}(\mathbf{I}_{nd} + (1-u)t\mathbf{U}_d\mathbf{J}_\rho)^{-1}\mathbf{U}_d\mathbf{L}) \\
&= \det(\mathbf{I}_{nd} + (1-u)t^2\tilde{\mathbf{D}}(D) \otimes \mathbf{I}_d - t \sum_{g \in \Gamma} \mathbf{A}_{1,g} \otimes \rho(g) - t \sum_{g \in \Gamma} \mathbf{A}_{0,g} \otimes \rho(g)),
\end{aligned}$$

Therefore, it follows that

$$\begin{aligned}
& \zeta_D(w, u, t, \rho, \alpha)^{-1} = \prod_{i=1}^{m_1} (1 - w(f_i)w(f_i^{-1})(1-u)^2t^2)^d \\
& \times \det(\mathbf{I}_{nd} + (1-u)t^2\mathbf{I}_d \otimes \tilde{\mathbf{D}}(D) - t \sum_{g \in \Gamma} \rho(g) \otimes \mathbf{A}_{1,g} - t \sum_{g \in \Gamma} \rho(g) \otimes \mathbf{A}_{0,g}),
\end{aligned}$$

□

By Theorems 6,8, the following result holds.

**Corollary 2** (Choe, Kwak, Park and Sato). *Let  $D$  be a connected digraph,  $\Gamma$  a finite group,  $\alpha : A(D) \rightarrow \Gamma$  a pseudo ordinary voltage assignment and  $\mathbf{W} = \mathbf{W}(D)$  a weighted matrix of  $D$ . Then we have*

$$\zeta(D^\alpha, \tilde{w}, u, t) = \prod_{\rho} \zeta_D(w, u, t, \rho, \alpha)^{\deg \rho},$$

where  $\rho$  runs over all inequivalent irreducible representations of  $\Gamma$ .

## 6 Bartholdi edge zeta function of a digraph

Let  $D$  be a connected digraph with  $m$  arcs  $e_1, \dots, e_m$ . Furthermore, let  $z_1, \dots, z_m$  be  $m$  variables. Set  $z_{e_i} = z_i$  ( $1 \leq i \leq m$ ) and  $\mathbf{z} = (z_1, \dots, z_m)$ . Then the *Bartholdi edge zeta function*  $\zeta(D, \mathbf{z}, u)$  of  $D$  is defined by

$$\zeta(D, \mathbf{z}, u) = \prod_{[C]} (1 - g(C)u^{bc(C)})^{-1},$$

where  $[C]$  runs over all equivalence classes of prime cycles of  $D$ . If  $D = D_G$  is the symmetric digraph of a graph  $G$ , then the Bartholdi edge zeta function  $\zeta(D_G, \mathbf{z}, u)$  of  $D_G$  is called the *Bartholdi edge zeta function*  $\zeta(G, \mathbf{z}, u)$  of  $G$ .

Now, set  $|V(D)| = n$ . Then we define an  $n \times n$  matrix  $\mathbf{A}'_1 = \mathbf{A}'_1(D) = (a_{xy})$  as follows:

$$a_{xy} = \begin{cases} z_{(x,y)}/(1 - z_{(x,y)}z_{(y,x)}(1 - u)^2) & \text{if both } (x, y) \text{ and } (y, x) \in A(D), \\ 0 & \text{otherwise.} \end{cases}$$

Furthermore, an  $n \times n$  matrix  $\mathbf{D}' = \mathbf{D}'(D) = (d_{xy})$  is the diagonal matrix defined by

$$d_{xx} = \sum_{o(e)=x, e^{-1} \in A(D)} \frac{z_e z_{e^{-1}}}{1 - z_e z_{e^{-1}}(1 - u)^2}.$$

Substituting  $t = 1$  in Theorem 5, we obtain the following result.

**Corollary 3.** *Let  $D$  be a connected digraph with  $m$  arcs and let  $\mathbf{z} = (z_1, \dots, z_m)$  be  $m$  variables. Then the reciprocal of the Bartholdi edge zeta function of  $D$  is given by*

$$\zeta(D, \mathbf{z}, u)^{-1} = \det(\mathbf{I}_n + (1 - u)\mathbf{D}' - \mathbf{A}'_1(D) - \tilde{\mathbf{A}}_0) \prod_{i=1}^{m_1} (1 - z_{f_i} z_{f_i^{-1}}(1 - u)^2),$$

where  $n = |V(D)|$  and  $f_1^{\pm 1}, \dots, f_{m_1}^{\pm 1}$  are symmetric arcs of  $D$ .

If  $D = D_G$ , then

**Corollary 4.** *Let  $G$  be a connected graph with  $m$  edges and let  $\mathbf{z} = (z_1, \dots, z_{2m})$  be  $2m$  variables and let  $\mathbf{W} = \mathbf{W}(G)$  be a weighted matrix of  $G$ . Then the reciprocal of the Bartholdi edge zeta function of  $G$  is given by*

$$\zeta(G, \mathbf{z}, u)^{-1} = \det(\mathbf{I}_n + (1 - u)\mathbf{D}' - \mathbf{A}'_1(G) - \tilde{\mathbf{A}}_0) \prod_{i=1}^m (1 - z_{f_i} z_{f_i^{-1}}(1 - u)^2),$$

where  $n = |V(G)|$  and  $D(G) = \{f_1^{\pm 1}, \dots, f_m^{\pm 1}\}$ .

## 7 Example

Finally, we give an example. Let  $D$  be the digraph with three vertices  $v_1, v_2, v_3$  and five arcs  $(v_1, v_2), (v_2, v_1), (v_2, v_3), (v_3, v_2), (v_3, v_1)$ . Furthermore, let

$$\mathbf{W}(D) = \begin{bmatrix} 0 & a & 0 \\ b & 0 & c \\ d & e & 0 \end{bmatrix}.$$

Then we have  $n = 3, m = 5, m_1 = 2$ . By Theorem 5, we have

$$\begin{aligned} & \zeta(D, w, u, t)^{-1} \\ &= (1 - ab(1 - u)^2t^2)(1 - ce(1 - u)^2t^2) \det(\mathbf{I}_3 - t\tilde{\mathbf{A}}_1 - t\tilde{\mathbf{A}}_0 + (1 - u)t^2\tilde{\mathbf{D}}) \\ &= AB \det \left( \begin{bmatrix} 1 + abF/A & -at/A & 0 \\ -bt/A & 1 + abF/A + ceF/B & -ct/B \\ -dt & -et/B & 1 + ceF/B \end{bmatrix} \right) \\ &= 1 - (ab + ce)u^2t^2 + abce(u^4 - u^2)t^4 - acdt^3, \end{aligned}$$

where  $A = 1 - ab(1 - u)^2t^2$ ,  $B = 1 - ce(1 - u)^2t^2$  and  $F = (1 - u)t^2$ .

Let  $\Gamma = Z_3 = \{1, \tau, \tau^2\} (\tau^3 = 1)$  be the cyclic group of order 3, and let  $\alpha : A(D) \rightarrow Z_3$  be the pseudo ordinary voltage assignment such that  $\alpha(v_1, v_2) = \tau$ ,  $\alpha(v_2, v_1) = \tau^2$  and  $\alpha(v_2, v_3) = \alpha(v_3, v_2) = \alpha(v_3, v_1) = 1$ . The characters of  $Z_3$  are given as follows:  $\chi_i(\tau^j) = (\xi^i)^j$ ,  $0 \leq i, j \leq 2$ , where  $\xi = \frac{-1 + \sqrt{-3}}{2}$ .

Now, we present the weighted Bartholdi  $L$ -function  $\zeta_D(w, u, t, \chi_1, \alpha)$  of  $D$  associated with  $\chi_1$  and  $\alpha$ . Theorem 8 implies that

$$\begin{aligned} \zeta_D(w, u, t, \chi_1, \alpha)^{-1} &= AB \det(\mathbf{I}_3 - t \sum_{i=0}^2 \chi_1(\tau^i) \mathbf{A}_{1, \tau^i} - t \sum_{i=0}^2 \chi_1(\tau^i) \mathbf{A}_{0, \tau^i} + (1 - u)t^2\tilde{\mathbf{D}}) \\ &= AB \det \left( \begin{bmatrix} 1 + abF/A & -at\xi/A & 0 \\ -bt\xi^2/A & 1 + abF/A + ceF/B & -ct/B \\ -dt & -et/B & 1 + ceF/B \end{bmatrix} \right) \\ &= 1 - (ab + ce)u^2t^2 + abce(u^4 - u^2)t^4 - acdt^3\xi. \end{aligned}$$

Similarly, we have

$$\zeta_D(w, u, t, \chi_2, \alpha)^{-1} = 1 - (ab + ce)u^2t^2 + abce(u^4 - u^2)t^4 - acdt^3\xi^2.$$

By Corollary 2, it follows that

$$\begin{aligned} \zeta(D^\alpha, \tilde{w}, u, t)^{-1} &= \zeta(D, w, u, t)^{-1} \zeta_D(w, u, t, \chi_1, \alpha)^{-1} \zeta_D(w, u, t, \chi_2, \alpha)^{-1} \\ &= (1 - (ab + ce)u^2t^2 + abce(u^4 - u^2)t^4)^3 - a^3c^3d^3t^9. \end{aligned}$$

If  $w(e^{-1}) = w(e)^{-1}$  for each symmetric arc  $e \in A(D)$ , then

$$\zeta(D, w, u, t)^{-1} = 1 - 2u^2t^2 + (u^4 - u^2)t^4 - acdt^3,$$

$$\zeta_D(w, u, t, \chi_i, \alpha)^{-1} = 1 - 2u^2t^2 + (u^4 - u^2)t^4 - acdt^3\zeta^i \quad (i = 1, 2)$$

and

$$\zeta(D^\alpha, \tilde{w}, u, t)^{-1} = (1 - 2u^2t^2 + (u^4 - u^2)t^4)^3 - a^3c^3d^3t^9.$$
