#### Abstract

We study the class of edge-transitive graphs of square-free order and valency at most $k$. It is shown that, except for a few special families of graphs, only finitely many members in this class are basic (namely, not a normal multicover of another member). Using this result, we determine the automorphism groups of locally primitive arc-transitive graphs with square-free order.

Keywords: edge-transitive graph; arc-transitive graph; stabilizer; quasiprimitive permutation group; almost simple group

## 1 Introduction

For a graph $\Gamma=(V, E)$, the number of vertices $|V|$ is called the order of $\Gamma$. A graph $\Gamma=(V, E)$ is called edge-transitive if its automorphism group Aut $\Gamma$ acts transitively on the edge set $E$. For convenience, denote by $\operatorname{ETSQF}(k)$ the class of connected edge-transitive graphs with square-free order and valency at most $k$.

The study of special subclasses of ETSQF $(k)$ has a long history, see for example [1, 4, $5,17,18,21,22,23]$ for those graphs of order being a prime or a product of two primes.

[^0]Recently, several classification results about the class ETSQF $(k)$ were given. Feng and Li [9] gave a classification of one-regular graphs of square-free order and prime valency. By Li et al. $[12,14]$, one may obtain a classification of vertex-transitive and edge-transitive tetravalent graphs of square-free order. By Li et al. [13] and Liu and Lu [16], one may deduce an explicitly classification of ETSQF(3). In this paper, we give a characterization about the class ETSQF $(k)$.

A typical method for analyzing edge-transitive graphs is to take normal quotient. Let $\Gamma=(V, E)$ be a connected graph such that a subgroup $G \leqslant A u t \Gamma$ acts transitively on $E$. Let $N$ be a normal subgroup of $G$, denoted by $N \triangleleft G$. Then either $N$ is transitive on $V$, or each $N$-orbit is an independent set of $\Gamma$. Let $V_{N}$ be the set of all $N$-orbits on $V$. The normal quotient $\Gamma_{N}$ (with respect to $G$ and $N$ ) is defined as the graph with vertex set $V_{N}$ such that distinct vertices $B, B^{\prime} \in V_{N}$ are adjacent in $\Gamma_{N}$ if and only if some $\alpha \in B$ and some $\alpha^{\prime} \in B^{\prime}$ are adjacent in $\Gamma$. We call $\Gamma_{N}$ non-trivial if $N \neq 1$ and $\left|V_{N}\right| \geqslant 3$. It is well-known and easily shown that $\Gamma_{N}$ is an edge-transitive graph. Moreover, if all $N$-orbits have the same length (which is obvious if $G$ is transitive on $V$ ), then $\Gamma_{N}$ is a regular graph of valency a divisor of the valency of $\Gamma$; in this case, $\Gamma$ is called a normal multicover of $\Gamma_{N}$.

A member in $\operatorname{ETSQF}(k)$ is called basic if it has no non-trivial normal quotients. Then every member in $\operatorname{ETSQF}(k)$ is a multicover of some basic member, or has a non-regular normal quotient (which might occur for vertex-intransitive graphs). Thus, to a great extent, basic members play an important role in characterizing the graphs in $\operatorname{ETSQF}(k)$. The first result of this paper shows that, except for a few special families of graphs, there are only finitely many basic members in $\operatorname{ETSQF}(k)$.

Theorem 1. Let $\Gamma=(V, E)$ be a connected graph of square-free order and valency $k \geqslant 3$. Assume that $G \leqslant A u t \Gamma$ acts transitively on $E$ and that each non-trivial normal subgroup of $G$ has at most 2 orbits on $V$. Then one of the following holds:
(1) $\Gamma$ is a complete bipartite graph, and $G$ is described in (1) and (5) of Lemma 13;
(2) $G$ is one of the Frobenius groups $\mathbb{Z}_{p}: \mathbb{Z}_{k}$ and $\mathbb{Z}_{p}: \mathbb{Z}_{2 k}$, where $p$ is a prime;
(3) $\operatorname{soc}(G)=\mathrm{M}_{11}, \mathrm{M}_{12}, \mathrm{M}_{22}, \mathrm{M}_{23}, \mathrm{M}_{24}$ or $\mathrm{J}_{1}$;
(4) $G=\mathrm{A}_{n}$ or $\mathrm{S}_{n}$ with $n<3 k$;
(5) $G=\operatorname{PSL}(2, p)$ or $\operatorname{PGL}(2, p)$;
(6) $\operatorname{soc}(G)=\operatorname{PSL}\left(2, p^{f}\right)$ with $f \geqslant 2$ and $p^{f}>9$, and either $k$ is divisible by $p^{f-1}$ or $f=2$ and $k$ is divisible by $p+1$;
(7) $\operatorname{soc}(G)=\operatorname{Sz}\left(2^{f}\right)$ and $k$ is divisible by $2^{2 f-1}$;
(8) $G$ is of Lie type defined over $\mathrm{GF}\left(p^{f}\right)$ with $p \leqslant k$, and either
(i) $\left[\frac{d}{2}\right] f<k$, and $G$ is a d-dimensional classical group with $d \geqslant 3$; or
(ii) $2 f<k$, and $\operatorname{soc}(G)=\mathrm{G}_{2}\left(p^{f}\right),{ }^{3} \mathrm{D}_{4}\left(p^{f}\right), \mathrm{F}_{4}\left(p^{f}\right),{ }^{2} \mathrm{E}_{6}\left(p^{f}\right)$, or $\mathrm{E}_{7}\left(p^{f}\right)$.

Remark 2 (Remarks on Theorem 1). For a finite group $G$, the $\operatorname{socle} \operatorname{soc}(G)$ of $G$ is the subgroup generated by all minimal normal subgroups of $G$. A finite group is called almost simple if $\operatorname{soc}(G)$ is a non-abelian simple group.
(a) The groups $G$ in case (1) are known except for $G$ being almost simple.
(b) The vertex-transitive graphs in case (5) are characterized in Theorem 27.
(c) Some properties about the graphs in cases (6)-(7) are given in Lemmas 14 and 15, respectively.

It would be interest to give further characterization for some special cases.
Problem 3. (i) Characterize edge-transitive graphs of square-free order which admits a group with socle $\operatorname{PSL}(2, q), \mathrm{Sz}(q), \mathrm{A}_{n}$ or a sporadic simple group.
(ii) Classify edge-transitive graphs of square-free order of small valencies.

For a graph $\Gamma=(V, E)$ and $G \leqslant$ Aut $\Gamma$, the graph $\Gamma$ is called $G$-locally primitive if, for each $\alpha \in V$, the stabilizer of $\alpha$ in $G$ induces a primitive permutation group on the neighbors of $\alpha$ in $\Gamma$. The second result of this paper determines, on the basis of Theorem 1 , the automorphism groups of locally primitive arc-transitive graphs of square-free order.

Theorem 4. Let $\Gamma=(V, E)$ be a connected $G$-locally primitive graph of square-free order and valency $k \geqslant 3$. Assume that $G$ is transitive on $V$ and that $\Gamma$ is not a complete bipartite graph. Then one of the following statements is true.
(1) $G=\mathrm{D}_{2 n}: \mathbb{Z}_{k}, 2 n k$ is square-free, $k$ is the smallest prime divisor of $n k$, and $\Gamma$ is a bipartite Cayley graph of the dihedral group $\mathrm{D}_{2 n}$;
(2) $G=M: X$, where $M$ is of square-free order, $X$ is almost simple with socle $T$ descried as in (3)-(6) and (8) of Theorem 1 such that $M T=M \times T, T$ has at most two orbits on $V$ and $\Gamma$ is $T$-edge-transitive; in particular, if $T=\operatorname{PSL}(2, p)$, then $M, T_{\alpha}$ and $k$ are listed in Table 3, where $\alpha \in V$.

## 2 Preliminaries

Let $\Gamma=(V, E)$ be a graph without isolated vertices, and let $G \leqslant A u t \Gamma$. The graph $\Gamma$ is said to be $G$-vertex-transitive or $G$-edge-transitive if $G$ acts transitively on $V$ or $E$, respectively. Recall that an arc in $\Gamma$ is an ordered pair of adjacent vertices. The graph $\Gamma$ is called $G$-arc-transitive if $G$ acts transitively on the set of $\operatorname{arcs}$ of $\Gamma$. For a vertex $\alpha \in V$, we denote by $\Gamma(\alpha)$ the set of neighbors of $\alpha$ in $\Gamma$, and by $G_{\alpha}$ the stabilizer of $\alpha$ in $G$. Then it is easily shown that $\Gamma$ is $G$-arc-transitive if and only if $\Gamma$ is $G$-vertex-transitive and, for $\alpha \in V$, the vertex-stabilizer $G_{\alpha}$ acts transitively on $\Gamma(\alpha)$.

Let $\Gamma=(V, E)$ be a connected $G$-edge-transitive graph. Note that each edge of $\Gamma$ gives two arcs. Then either $\Gamma$ is $G$-arc-transitive or $G$ has exactly two orbits (of the same size $|E|$ ) on the arc set of $\Gamma$. If $\Gamma$ is not $G$-vertex-transitive then $\Gamma$ is a bipartite graph and, for $\alpha \in V$, the stabilizer $G_{\alpha}$ acts transitively on $\Gamma(\alpha)$. If $\Gamma$ is $G$-arc-transitive, then there exists $g \in G \backslash G_{\alpha}$ such that $(\alpha, \beta)^{g}=(\beta, \alpha)$ and, since $\Gamma$ is connected, $\left\langle g, G_{\alpha}\right\rangle=G$; obviously, this $g$ can be chosen as a 2-element in $\mathbf{N}_{G}\left(G_{\alpha \beta}\right)$ with $g^{2} \in G_{\alpha \beta}$, where $G_{\alpha \beta}=G_{\alpha} \cap G_{\beta}$. Suppose that $\Gamma$ is $G$-vertex-transitive but not $G$-arc-transitive. Then the arc set of $\Gamma$ is partitioned into two $G$-orbits $\Delta$ and $\Delta^{*}$, where $\Delta^{*}=\{(\alpha, \beta) \mid(\beta, \alpha) \in \Delta\}$. Thus, for $\alpha \in V$, the set $\Gamma(\alpha)$ is partitioned into two $G_{\alpha}$-orbits $\Delta(\alpha)=\{\beta \mid(\alpha, \beta) \in \Delta\}$ and $\Delta^{*}(\alpha)=\{\beta \mid(\beta, \alpha) \in \Delta\}$, which have equal size. Then we have the next lemma.

Lemma 5. Let $\Gamma=(V, E)$ be a connected $G$-edge-transitive graph, and $\{\alpha, \beta\} \in E$. Then one of the following holds.
(1) The stabilizer $G_{\alpha}$ is transitive on $\Gamma(\alpha),|\Gamma(\alpha)|=\left|G_{\alpha}: G_{\alpha \beta}\right|$, and either
(i) $G$ is intransitive on $V$; or
(ii) $G=\left\langle g, G_{\alpha}\right\rangle$ for a 2-element $g \in \mathbf{N}_{G}\left(G_{\alpha \beta}\right) \backslash G_{\alpha}$ with $(\alpha, \beta)^{g}=(\beta, \alpha)$ and $g^{2} \in G_{\alpha \beta}$.
(2) $\Gamma$ is $G$-vertex-transitive, $G_{\alpha}$ has exactly two orbits on $\Gamma(\alpha)$ of the same size $\mid G_{\alpha}$ : $G_{\alpha \beta} \mid ;$ in particular, $|\Gamma(\alpha)|=2\left|G_{\alpha}: G_{\alpha \beta}\right|$.
Let $\Gamma=(V, E)$ be a regular graph and $G \leqslant \operatorname{Aut} \Gamma$. For $\alpha \in V$, the stabilizer $G_{\alpha}$ induces a permutation group $G_{\alpha}^{\Gamma(\alpha)}$ (on $\left.\Gamma(\alpha)\right)$. Let $G_{\alpha}^{[1]}$ be the kernel of this action. Then $G_{\alpha}^{\Gamma(\alpha)} \cong G_{\alpha} / G_{\alpha}^{[1]}$. Considering the actions of Sylow subgroups of $G_{\alpha}^{[1]}$ on $V$, it is easily shown that the next lemma holds, see [7] for example.

Lemma 6. Let $\Gamma=(V, E)$ be a connected regular graph, $G \leqslant$ Aut $\Gamma$ and $\alpha \in V$. Assume that $G_{\alpha} \neq 1$. Let $p$ be a prime divisor of $\left|G_{\alpha}\right|$. Then $p \leqslant|\Gamma(\alpha)|$. If further $\Gamma$ is $G$-vertextransitive, then $p$ divides $\left|G_{\alpha}^{\Gamma(\alpha)}\right|$ and, for $\beta \in \Gamma(\alpha)$, each prime divisor of $\left|G_{\alpha \beta}\right|$ is less than $|\Gamma(\alpha)|$.

A permutation group $G$ on a set $\Omega$ is semiregular if $G_{\alpha}=1$ for each $\alpha \in \Omega$. A transitive permutation group is regular if further it is semiregular.

Lemma 7. Let $\Gamma$ be a connected $G$-vertex-transitive graph, $N \triangleleft G \leqslant$ Aut $\Gamma$ and $\alpha \in V$. Assume that $N_{\alpha}^{\Gamma(\alpha)}$ is semiregular on $\Gamma(\alpha)$. Then $N_{\alpha}^{[1]}=1$.

Proof. Let $\beta \in \Gamma(\alpha)$. Then $\beta=\alpha^{x}$ for some $x \in G$, and hence $N_{\beta}=N_{\alpha^{x}}=N \cap$ $G_{\alpha^{x}}=\left(N \cap G_{\alpha}\right)^{x}=\left(N_{\alpha}\right)^{x}$. It follows that $N_{\beta}^{\Gamma(\beta)}$ and $N_{\alpha}^{\Gamma(\alpha)}$ are permutation isomorphic; in particular, $N_{\beta}^{\Gamma(\beta)}$ is semiregular on $\Gamma(\beta)$. Thus $N_{\alpha}^{[1]}$ acts trivially on $\Gamma(\beta)$, and so $N_{\alpha}^{[1]}=N_{\beta}^{[1]}$. Since $\Gamma$ is connected, $N_{\alpha}^{[1]}$ fixes each vertex of $\Gamma$, hence $N_{\alpha}^{[1]}=1$.
Lemma 8. Let $\Gamma=(V, E)$ be a connected graph, $N \triangleleft G \leqslant$ Aut $\Gamma$ and $\alpha \in V$. Assume that either $N$ is regular on $V$, or $\Gamma$ is a bipartite graph such that $N$ is regular on both the bipartition subsets of $\Gamma$. Then $G_{\alpha}^{[1]}=1$.

Proof. Set $X=N G_{\alpha}^{[1]}$. Then $X_{\alpha}=G_{\alpha}^{[1]}$ and $X_{\alpha}^{[1]}=G_{\alpha}^{[1]}$, and hence $X_{\alpha}^{\Gamma(\alpha)}=1$.
Assume first that $N$ is regular on $V$. Then $G=N G_{\alpha}$. It follows that $X$ is normal in $G$. Thus our results follows from Lemma 7 .

Now assume that $\Gamma$ is a bipartite graph with bipartition subsets $U$ and $W$, and that $N$ is regular on both $U$ and $W$. Without loss of generality, we assume that $\alpha \in U$. Then $\Gamma(\alpha) \subseteq W$, and $X_{\alpha}=X_{\beta}$ for $\beta \in \Gamma(\alpha)$. Let $\gamma \in \Gamma(\beta)$. Then $\gamma \in U$. Set $E_{0}=\left\{\{\gamma, \beta\}^{x} \mid x \in X\right\}$. Then $\Sigma=\left(V, E_{0}\right)$ is a spanning subgraph of $\Gamma$, and $X$ acts transitively on $E_{0}$. Thus $\Sigma$ is a regular graph, and $X_{\alpha}$ is transitive on $\Sigma(\alpha)$. Noting $\Sigma(\alpha) \subseteq \Gamma(\alpha)$, it follows that $|\Sigma(\alpha)|=1$, and hence $\Sigma$ is a matching. In particular, $X_{\beta}=X_{\gamma}$. It follows that $G_{\alpha}^{[1]}=X_{\alpha}=X_{\beta}=X_{\gamma}$. Since all vertices in $U$ are equivalent under $X$, we have $X_{\gamma}$ acts trivially on $\Gamma(\gamma)$. Then a similar argument as above leads to $G_{\alpha}^{[1]}=X_{\gamma}=X_{\delta}=X_{\theta}$ for any $\delta \in \Gamma(\gamma)$ and $\theta \in \Gamma(\delta)$. Then, by the connectedness, we conclude that $G_{\alpha}^{[1]}$ fixes each vertex of $\Gamma$. Thus $G_{\alpha}^{[1]}=1$.

We end this section by quoting a known result.
Lemma 9 ([12]). Let $\Gamma=(V, E)$ be a connected $G$-edge-transitive graph, $N \triangleleft G \leqslant$ Aut $\Gamma$ and $\alpha \in V$. Then all $N_{\alpha}$-orbits on $\Gamma(\alpha)$ have the same length.

## 3 Complete bipartite graphs

We first list a well-known result in number theory. For integers $a>0$ and $n>0$, a prime divisor of $a^{n}-1$ is called primitive if it does not divide $a^{i}-1$ for any $0<i<n$.

Theorem 10 (Zsigmondy). For integers $a, n \geqslant 2$, if $a^{n}-1$ does not have primitive prime divisors, then either $(a, n)=(2,6)$, or $n=2$ and $a+1$ is a power of 2 .

Let $G$ be a permutation group on $V$, and let $x$ be a permutation on $V$ which centralizes $G$. If $x$ fixes some point $\alpha \in V$, then $x$ fixes $\alpha^{g}$ for each $g \in G$. Thus the next simple result follows.

Lemma 11. Let $G$ be a permutation group on $V$. Assume that $N$ is a normal transitive subgroup of $G$. Then the centralizer $\mathbf{C}_{G}(N)$ is semiregular on $V$, and $\mathbf{C}_{G}(N)=N$ if further $N$ is abelian.

Recall that a transitive permutation group $G$ is quasiprimitive if each non-trivial normal subgroup of $G$ is transitive. Let $G$ be a quasiprimitive permutation group on $V$, and let $\mathcal{B}$ be a $G$-invariant partition on $V$. Then $G$ induces a permutation group $G^{\mathcal{B}}$ on $\mathcal{B}$. Assume that $|\mathcal{B}| \geqslant 2$. Since $G$ is quasiprimitive, $G$ acts faithfully on $\mathcal{B}$. Then $G^{\mathcal{B}} \cong G$, and so $\operatorname{soc}\left(G^{\mathcal{B}}\right) \cong \operatorname{soc}(G)$.

Lemma 12. Let $G$ be a quasiprimitive permutation group of square-free degree. Then $\operatorname{soc}(G)$ is simple, so either $G$ is almost simple or $G \leqslant \operatorname{AGL}(1, p)$ for a prime $p$.

Proof. Let $G$ be a quasiprimitive permutation group on $V$ of square-free degree. Let $\mathcal{B}$ be a $G$-invariant partition on $V$ such that $|\mathcal{B}| \geqslant 2$ and $G^{\mathcal{B}}$ is primitive. Noting that $|\mathcal{B}|$ is
square-free, by [15], $\operatorname{soc}\left(G^{\mathcal{B}}\right)$ is simple. Thus $\operatorname{soc}(G) \cong \operatorname{soc}\left(G^{\mathcal{B}}\right)$ is simple, and the result follows.

Let $G$ be a permutation group on $V$. For a subset $U \subseteq V$, denote by $G_{U}$ and $G_{(U)}$ the subgroups of $G$ fixing $U$ set-wise and point-wise, respectively. For $X \leqslant G$ and an $X$-invariant subset $U$ of $V$, denote by $X^{U}$ the restriction of $X$ on $U$. Then $X^{U} \cong X / X_{(U)}$.

We now prove a reduction lemma for Theorem 1.
Lemma 13. Let $\Gamma=(V, E)$ be a connected $G$-edge-transitive graph of square-free order and valency $k \geqslant 3$, where $G \leqslant$ Аut $\Gamma$. Assume that each minimal normal subgroup of $G$ has at most two orbits on $V$. Then one of the following holds:
(1) $\Gamma \cong \mathrm{K}_{k, k}, k$ is an odd prime, $G \cong\left(\mathbb{Z}_{k}^{2}: \mathbb{Z}_{l}\right) \cdot \mathbb{Z}_{2}$ and $\Gamma$ is $G$-vertex-transitive, where $l$ is a divisor of $k-1$;
(2) $|V|=p$ with $p \geqslant 3$ prime, $k$ is even, $G \cong \mathbb{Z}_{p}: \mathbb{Z}_{k}$ and $\Gamma$ is $G$-vertex-transitive;
(3) $|V|=2 p$ with $p \geqslant 3$ prime, and $G$ is isomorphic to one of $\mathbb{Z}_{p}: \mathbb{Z}_{k}$ and $\mathbb{Z}_{p}: \mathbb{Z}_{2 k}$;
(4) $G$ is almost simple;
(5) $\Gamma \cong \mathrm{K}_{k, k}, \Gamma$ is $G$-vertex-transitive, $\operatorname{soc}(G)$ is the unique minimal normal subgroup of $G, \operatorname{soc}(G) \cong T^{2}$ for a nonabelian simple group $T$ and, for $\alpha \in V$, either
(i) $\operatorname{soc}(G)_{\alpha} \cong H \times T$ for a subgroup $H$ of $T$ with $k=\mid T$ : $H \mid$; or
(ii) $k=105, T \cong \mathrm{~A}_{7}$ and $\operatorname{soc}(G)_{\alpha} \cong \mathrm{A}_{6} \times \operatorname{PSL}(3,2)$.

Proof. Let $N$ be a minimal normal subgroup of $G$. Then $N$ is a directed product of isomorphic simple groups. Since $\Gamma$ has valency $k \geqslant 3$, we know that $|V|>3$. Since $|V|$ is square-free and $N$ has at most two orbits on $V$, we conclude that $N$ is not an elementary abelian 2-group. In particular, $N$ has no a subgroup of index 2.

Case 1. Assume first that $G$ has two distinct minimal normal subgroups $N$ and $M$. Then $N \cap M=1$, and hence $N M=N \times M$.

Suppose that both $N$ and $M$ are transitive on $V$. By Lemma 11, $N$ and $M$ are regular on $V$; in particular, $|N|=|M|=|V|$. Thus $N$ and $M$ are soluble, it implies that $N \cong M \cong \mathbb{Z}_{p}$ for an odd prime $p$. Again by Lemma $11, N=M$, a contradiction.

Without loss of generality, we assume that $N$ is intransitive on $V$. Then $\Gamma$ is a bipartite graph, whose bipartition subsets are $N$-orbits, say $U$ and $V \backslash U$. A similar argument as above paragraph yields that $M$ has no subgroups of index 2 . It follows that $M$ fixes both $U$ and $V \backslash U$ set-wise, and hence $U$ and $V \backslash U$ are two $M$-orbits on $V$.

Let $X=N M$ and $\Delta=U$ or $V \backslash U$. By Lemma 11, both $N^{\Delta}$ and $M^{\Delta}$ are regular subgroups of $X^{\Delta}$. Set $N \cong T^{i}$, where $T$ is a simple group. Then $N_{(\Delta)} \cong T^{j}$ for some $j<i$, and so $N^{\Delta} \cong N / N_{(\Delta)} \cong T^{i-j}$. It follows that $|\Delta|=\left|N^{\Delta}\right|=|T|^{i-j}$. Since $T$ is simple and $|\Delta|$ is square-free, $i-j=1$ and $N^{\Delta} \cong T \cong \mathbb{Z}_{p}$, where $p=|\Delta|$ is an odd prime. Similarly, $M^{\Delta} \cong \mathbb{Z}_{p}$, and so $M$ is abelian. In particular, $X=N \times M$ is abelian and $|X|$ is a power of $p$. It implies that $X^{\Delta} \cong \mathbb{Z}_{p}$. Then, by Lemma $11, N^{\Delta}=M^{\Delta}=X^{\Delta}$. Thus
$N \times M=X \leqslant X^{\Delta} \times X^{V \backslash \Delta} \cong \mathbb{Z}_{p}^{2}$. Then $X \cong \mathbb{Z}_{p}^{2}$, and hence $N \cong M \cong \mathbb{Z}_{p}$. Moreover, $X_{(\Delta)} \cong \mathbb{Z}_{p}$.

Let $\alpha \in \Delta$. Then $G_{\alpha} \geqslant X_{(\Delta)}$. By Lemma $6, k=|\Gamma(\alpha)| \geqslant p$, and so $\Gamma \cong \mathrm{K}_{p, p}$. Noting that $N$ is regular on $\Delta$ and $V \backslash \Delta$, by Lemma $8, G_{\alpha}$ acts faithfully on $\Gamma(\alpha)$, and so $G_{\alpha}$ is isomorphic to a subgroup of the symmetric group $\mathrm{S}_{p}$. Noting that $G_{\alpha}$ has a normal subgroup $X_{(\Delta)} \cong \mathbb{Z}_{p}$, it follows that $G_{\alpha}$ is isomorphic to a subgroup of the Frobenius group $\mathbb{Z}_{p}: \mathbb{Z}_{p-1}$. Write $G_{\alpha} \cong \mathbb{Z}_{p}: \mathbb{Z}_{l}$, where $l$ is a divisor of $p-1$. Then $G_{\Delta}=N G_{\alpha} \cong \mathbb{Z}_{p}^{2}: \mathbb{Z}_{l}$.

Clearly, $X_{(\Delta)}$ has at least $p+1$ orbits on $V$. Then, by the assumptions of this lemma, $X_{(\Delta)}$ is not normal in $G$. On the other hand, $\left(X_{(\Delta)}\right)^{g}=\left(X^{g}\right)_{\left(\Delta^{g}\right)}=X_{(\Delta)}$ for each $g \in G_{\Delta}$, yielding $X_{(\Delta)} \triangleleft G_{\Delta}$. It follows that $G \neq G_{\Delta}$, and hence $G$ is transitive on $V$. Note that $\left|G: G_{\Delta}\right| \leqslant 2$. Then part (1) of this lemma follows.

Case 2. Assume that $N:=\operatorname{soc}(G)$ is the unique minimal normal subgroup of $G$.
Assume that $N$ is simple. If $N$ is nonabelian then (4) occurs. Assume that $N \cong \mathbb{Z}_{p}$ for some odd prime $p$. Then $N$ is regular on each $N$-orbit on $V$. Thus $G_{\alpha}$ is faithful on $\Gamma(\alpha)$ by Lemma 8 , where $\alpha \in V$. Noting that $\mathbf{C}_{G}(N)$ is normal in $G$, we conclude that $\mathbf{C}_{G}(N)=N$. Thus $G / N=\mathbf{N}_{G}(N) / \mathbf{C}_{G}(N) \lesssim \operatorname{Aut}(N) \cong \mathbb{Z}_{p-1}$, and so $G \lesssim \operatorname{AGL}(1, p)$. Set $G \cong \mathbb{Z}_{p}: \mathbb{Z}_{m}$, where $m$ is a divisor of $p-1$. Let $\alpha \in U$. Then $G_{\alpha} \cong N G_{\alpha} / N \leqslant$ $G / N \cong \mathbb{Z}_{m}$; in particular, $G_{\alpha}$ is cyclic. Recalling that $G_{\alpha}$ is faithful on $\Gamma(\alpha)$, it implies that $G_{\alpha} \cong \mathbb{Z}_{k}$. Thus one of (2) and (3) occurs by noting that $\left|G:\left(N G_{\alpha}\right)\right| \leqslant 2$.

In the following we assume that $N \cong T^{l}$ for an integer $l \geqslant 2$ and a simple group $T$. If $N$ is transitive on $V$ then $G$ is quasiprimitive on $V$, and hence $\operatorname{soc}(G)=N$ is simple by Lemma 12, a contradiction. If $G$ is intransitive on $V$, then $G$ is faithful on each of its orbits, and then $N$ is simple by Lemma 12, again a contradiction. Thus, in the following, we assume further that $\Gamma$ is $G$-vertex-transitive and $N$ has two orbits $U$ and $W$ on $V$. Note that $|U|=|W|=\frac{|V|}{2}$ is odd and square-free.

Since $\Gamma$ is $G$-vertex-transitive, $\left|G: G_{U}\right|=2$. Let $x \in G \backslash G_{U}$. Then $G=G_{U}\langle x\rangle$, $x^{2} \in G_{U}, U^{x}=W$ and $W^{x}=U$. Let $\mathcal{B}$ be a $G_{U}$-invariant partition of $U$ such that $\left(G_{U}\right)^{\mathcal{B}}$ is primitive. Set $\mathcal{C}=\left\{B^{x} \mid B \in \mathcal{B}\right\}$. Then $\left(G_{U}\right)^{\mathcal{C}}$ is also primitive. By [15], both $\operatorname{soc}\left(\left(G_{U}\right)^{\mathcal{B}}\right)$ and $\operatorname{soc}\left(\left(G_{U}\right)^{\mathcal{C}}\right)$ are simple. Then $\operatorname{soc}\left(\left(G_{U}\right)^{\mathcal{B}}\right) \cong \operatorname{soc}\left(\left(G_{U}\right)^{\mathcal{C}}\right) \cong T$. Let $K$ be the kernel of $G_{U}$ acting on $\mathcal{B}$. Then $K^{x}$ is the kernel of $G_{U}$ acting on $\mathcal{C}$, and $K^{x^{2}}=K$. Since $K, K^{x} \triangleleft G_{U}$, we have $K \cap K^{x} \triangleleft G_{U}$. Noting that $\left(K \cap K^{x}\right)^{x}=K \cap K^{x}$, it follows that $K \cap K^{x} \triangleleft G$. Since $K \cap K^{x}$ has at least $2|\mathcal{B}|>2$ orbits on $V$, we have $K \cap K^{x}=1$. Then $G_{U} \lesssim G_{U} / K \times G_{U} / K^{x} \cong\left(G_{U}\right)^{\mathcal{B}} \times\left(G_{U}\right)^{\mathcal{C}}$, yielding $N \cong T^{2}$.

We claim that $T$ is a nonabelian simple group. Suppose that $T \cong \mathbb{Z}_{p}$ for some (odd) prime $p$. Then $\left(G_{U}\right)^{\mathcal{B}} \cong\left(G_{U}\right)^{\mathcal{C}} \lesssim \mathbb{Z}_{p}: \mathbb{Z}_{p-1}$, and so $G=G_{U} \cdot \mathbb{Z}_{2} \lesssim\left(\left(\mathbb{Z}_{p}: \mathbb{Z}_{p-1}\right) \times\right.$ $\left.\left(\mathbb{Z}_{p}: \mathbb{Z}_{p-1}\right)\right) . \mathbb{Z}_{2}$. Let $H$ be a $p^{\prime}$-Hall subgroup of $G$ with $x \in H$. Then $G=N: H$, $H \lesssim\left(\mathbb{Z}_{p-1} \times \mathbb{Z}_{p-1}\right) \cdot \mathbb{Z}_{2}$. Moreover, $H_{U}$ is $p^{\prime}$-Hall subgroup of $G_{U}, H=H_{U}\langle x\rangle$ and $H_{U} \lesssim \mathbb{Z}_{p-1} \times \mathbb{Z}_{p-1}$. Note that $N$ is the unique minimal normal subgroup of $G$. Then $H$ is maximal in $G$, and thus $G$ can be viewed as a primitive subgroup of the affine group AGL $(2, p)$. Since $H_{U}$ is an abelian normal subgroup of $H$, by [19, 2.5.10], $H_{U}$ is cyclic. It follows that $H_{U} \lesssim \mathbb{Z}_{p-1}$. Since $H_{U}$ has index 2 in $H$, by [19, 2.5.7], $H_{U}$ is an irreducible subgroup of $\mathrm{GL}(2, p)$. Then, by $[19,2.3 .2],\left|H_{U}\right|$ is not a divisor of $p-1$, a contradiction. Therefore, $T$ is a nonabelian simple group.

Set $N=T_{1} \times T_{2}$, where $T_{1} \cong T_{2} \cong T$. Since $T_{1}$ and $T_{2}$ are isomorphic nonabelian simple groups, $T_{1}$ and $T_{2}$ are the only non-trivial normal subgroups of $N$. Thus $N_{(U)} \in\left\{1, T_{1}, T_{2}\right\}$. For $g \in G_{U}$, we have $\left(N_{(U)}\right)^{g}=\left(N^{g}\right)_{\left(U^{g}\right)}=N_{(U)}$. Thus $N_{(U)} \triangleleft G_{U}$. Let $x \in G \backslash G_{U}$. Then $U^{x}=W$ and $W^{x}=U$, yielding $\left(N_{(U)}\right)^{x}=N_{(W)}$ and $\left(N_{(W)}\right)^{x}=N_{(U)}$. It follows that either $\left\{N_{(U)}, N_{(W)}\right\}=\left\{T_{1}, T_{2}\right\}$ or $N$ is faithful on both $U$ and $W$. The former case yields that $N_{(U)}$ acts transitively on $W$, and so (i) of part (5) follows.

Assume that $N$ is faithful on both $U$ and $W$. Then neither $T_{1}$ nor $T_{2}$ is transitive on $U$. Let $\mathcal{O}$ be the set of $T_{1}$-orbits on $U$, and let $O \in \mathcal{O}$. Then $T_{2}$ is transitive on $\mathcal{O}$. Thus $T$ has two transitive permutation representations of degrees $|O|$ and $|\mathcal{O}|$, respectively. Then $T$ has two primitive permutation representations of degrees $n_{1}$ and $n_{2}$, where $n_{1}>1$ is a divisor of $|O|$ and $n_{2}>1$ is a divisor of $|\mathcal{O}|$. Since $|V|=2|U|=2|O||\mathcal{O}|$ is square-free, $n_{1}$ and $n_{2}$ are odd, square-free and coprime. Inspecting [15, Tables 1-4], we conclude that $T$ is either an alternating group or a classical group of Lie type.

Suppose that $T=\operatorname{PSL}(d, q)$ with $d \geqslant 3$. By the Atlas [8], neither $\operatorname{PSL}(3,2)$ nor $\operatorname{PSL}(4,2)$ has maximal subgroups of coprime indices. Thus we assume that $(d, q) \neq(3,2)$ or $(4,2)$. Then, by [15, Table 3],

$$
\left\{n_{1}, n_{2}\right\} \subseteq\left\{\left.\frac{\prod_{j=0}^{i-1}\left(q^{m-j}-1\right)}{\prod_{j=1}^{i}\left(q^{j}-1\right)} \right\rvert\, 1 \leqslant i<d\right\} \cup\left\{\left.\frac{\prod_{j=0}^{2 i-1}\left(q^{m-j}-1\right)}{\left(\prod_{j=1}^{i}\left(q^{j}-1\right)\right)^{2}} \right\rvert\, 1 \leqslant i<\frac{d}{2}\right\}
$$

If $q^{d}-1$ has a primitive prime divisor $r$, then both $n_{1}$ and $n_{2}$ are divisible by $r$, which is not possible. Thus $q^{d}-1$ has no primitive prime divisor, and so $(q, d)=(2,6)$ by Theorem 10. Computation of $n_{1}$ and $n_{2}$ shows that this is not the case.

Similarly, we exclude other classes of classical groups of Lie type except for $\operatorname{PSL}\left(2, p^{f}\right)$, where $p$ is a prime. By the Atlas [8], we exclude $\operatorname{PSL}\left(2, p^{f}\right)$ while $p^{f} \leqslant 31$. Suppose that $T=\operatorname{PSL}\left(2, p^{f}\right)$ with $p^{f} \geqslant 32$. By [15, Table 3], one of $n_{1}$ and $n_{2}$ is $p^{f}+1$ and the other one is divisible by $p$. This is not possible since one of $p^{f}+1$ and $p$ is even.

Now let $T=\mathrm{A}_{c}$ for some $c \geqslant 5$. By the above argument, we may assume that $\mathrm{A}_{c}$ is not isomorphic to a classical simple group of Lie type. Then $c \neq 5,6$ or 8 . Note that for $c \geqslant 5$ and $a<b<\frac{c}{2}$, the binomial coefficient $\binom{c}{b}=\binom{c}{a}\binom{c-a}{b-a} /\binom{b}{b-a}$. It is easily shown that $\binom{c}{a}>\binom{b}{b-a}=\binom{b}{a}$; in particular, $\binom{c}{a}$ is not a divisor of $\binom{b}{b-a}$. Thus $\binom{c}{a}$ and $\binom{c}{b}$ are not comprime, and so at most one of $n_{1}$ and $n_{2}$ equals to a binomial coefficient. Checking the actions listed in [15, Table 1] implies that either $c=7$, or $c=2 a$ for $a \in\{6,9,10,12,36\}$. Suppose the later case occurs. Then one of $n_{1}$ and $n_{2}$ is $\frac{1}{2}\left({ }_{a}^{a a}\right)$ and the other one is a binomial coefficient, say $\left({ }_{b}^{2 a}\right)$. But computation shows that such two integers are not coprime, a contradiction. Therefore, $T=\mathrm{A}_{7}$.

Checking the subgroups of $\mathrm{A}_{7}$, we conclude that $\left\{n_{1}, n_{2}\right\}=\{|O|,|\mathcal{O}|\}=\{7,15\}$. Take $\alpha \in O$. Recall that $\Gamma$ is $G$-vertex-transitive. Then there is an element $x \in G \backslash G_{U}$ such that $\left\{\alpha, \alpha^{x}\right\} \in E, U^{x}=W$ and $W^{x}=U$. Since $N=T_{1} \times T_{2}$ is the unique minimal normal subgroup of $G$, we know that $T_{1}^{x}=T_{2}$ and $T_{2}^{x}=T_{1}$. It follows $O^{x}$ is a $T_{2}$-orbit on $W$, and so $\mathcal{O}^{x}:=\left\{O^{h x} \mid h \in G_{U}\right\}$ is the set of $T_{2}$-orbits on $W$. Moreover, $T_{1}$ acts transitively on $\mathcal{O}^{x}$. Note that $|O|=\left|O^{x}\right|$ and $|\mathcal{O}|=\left|\mathcal{O}^{x}\right|$. Thus, without loss of generality, we may assume that $|O|=7$ and $|\mathcal{O}|=15$. Then $\left(T_{2}\right)_{O} \cong \operatorname{PSL}(3,2)$ and $\left(T_{1}\right)_{\alpha} \cong \mathrm{A}_{6}$, where $\alpha \in O$. Recall
that $T_{2}$ is intransitive on $V$. Since $T_{2} \triangleleft N$ and $N$ is transitive on $U$, we conclude that each $T_{2}$-orbit on $U$ has size 15. It follows that $\left(T_{2}\right)_{O}=\left(T_{2}\right)_{\alpha}$. Then $N_{\alpha} \geqslant\left(T_{1}\right)_{\alpha} \times\left(T_{2}\right)_{\alpha}$, and so $N_{\alpha}=\left(T_{1}\right)_{\alpha} \times\left(T_{2}\right)_{\alpha} \cong \mathrm{A}_{6} \times \operatorname{PSL}(3,2)$ as $\left|N: N_{\alpha}\right|=|U|=|O||\mathcal{O}|=105$. Note that $N_{\alpha^{x}}=\left(N_{\alpha}\right)^{x}=\left(\left(T_{1}\right)_{\alpha} \times\left(T_{2}\right)_{\alpha}\right)^{x}=\left(T_{2}\right)_{\alpha^{x}} \times\left(T_{1}\right)_{\alpha^{x}}$. Then it is easily shown that $N_{\alpha} \cap N_{\alpha^{x}}=\left(\left(T_{1}\right)_{\alpha} \cap\left(T_{1}\right)_{\alpha^{x}}\right) \times\left(\left(T_{2}\right)_{\alpha} \cap\left(T_{2}\right)_{\alpha^{x}}\right) \cong \mathrm{S}_{4} \times \mathrm{S}_{4}$. By the choice of $x$, we conclude that $|\Gamma(\alpha)| \geqslant\left|N_{\alpha}:\left(N_{\alpha} \cap N_{\alpha^{x}}\right)\right| \geqslant 105$. Thus $\Gamma=\mathrm{K}_{105,105}$, and hence (ii) of part (5) occurs.

## 4 Graphs associated with $\operatorname{PSL}\left(2, p^{f}\right)$ and $\mathrm{Sz}\left(2^{f}\right)$

Let $\Gamma=(V, E)$ be a connected graph of square-free order and valency $k$. Assume that $G \leqslant$ Aut $\Gamma$ is almost simple with socle $T$. Assume further that $G$ is transitive on $E$ and that $T$ has at most two orbits on $V$. Let $\{\alpha, \beta\} \in E$. Then $\left|T_{\alpha}\right|=\left|T_{\beta}\right|$ as $\Gamma$ is a regular graph. Then $\left|T_{\beta}: T_{\alpha \beta}\right|=\left|T_{\alpha}: T_{\alpha \beta}\right|$ and, by Lemma $9,\left|T_{\alpha}: T_{\alpha \beta}\right|$ is a divisor of $k=|\Gamma(\alpha)|$. Moreover, since $|V|$ is square-free, it is easily shown that $T_{\alpha} \neq T_{\beta}$.

Lemma 14. Let $\Gamma=(V, E)$ be a connected $G$-edge-transitive graph of square-free order and valency $k$. Assume that $\operatorname{soc}(G)=\operatorname{PSL}\left(2, p^{f}\right)$ with $f \geqslant 2$ and $p^{f}>9$, and that $\operatorname{soc}(G)$ has at most two orbits on $V$. Then one of the following statements holds:
(i) $f=2, T_{\alpha}=\operatorname{PGL}(2, p)$ or $\operatorname{PSL}(2, p)$, and $k$ is divisible by $p$ or $p+1$;
(ii) $T_{\alpha}=\mathbb{Z}_{p}^{f-1}: \mathbb{Z}_{l}$ for a divisor $l$ of $p-1$, and $k$ is divisible by $p^{f-1}$; further, if $\Gamma$ is $G$-locally primitive then $k=p^{f-1}$;
(iii) $T_{\alpha}=\mathbb{Z}_{p}^{f}: \mathbb{Z}_{l}$ for a divisor l of $p^{f}-1$, and $k$ is divisible by $p^{f}$; further, if $\Gamma$ is $G$-locally primitive then $k=p^{f}$.

Proof. Let $T=\operatorname{soc}(G)$. Take $\alpha \in V$ and a maximal subgroup $M$ of $T$ with $T_{\alpha} \leqslant M$. Then both $|T: M|$ and $\left|M: T_{\alpha}\right|$ are square-free as $\left|T: T_{\alpha}\right|$ is square-free. By [15], either $M=\mathbb{Z}_{p}^{f}: \mathbb{Z}_{\frac{p^{f}-1}{(2, p-1)}}$ and $|T: M|=p^{f}+1$, or $f=2, M=\operatorname{PGL}(2, p)$ and $|T: M|=\frac{p\left(p^{2}+1\right)}{2}$.

Assume that $T_{\alpha}$ is insoluble. Then $f=2$ and $T_{\alpha}=\operatorname{PGL}(2, p)$ or $\operatorname{PSL}(2, p)$. Let $\beta \in \Gamma(\alpha)$. Recall that $T_{\alpha} \neq T_{\beta}$ and $\left|T_{\beta}: T_{\alpha \beta}\right|=\left|T_{\alpha}: T_{\alpha \beta}\right|$ is a divisor of $k$. If $T_{\alpha}=\operatorname{PSL}(2, p)$ then, by [11, II.8.27], $\left|T_{\alpha}: T_{\alpha \beta}\right|$ is divisible by $p$ or $p+1$. Suppose that $T_{\alpha}=\mathrm{PGL}(2, p)$. Then $T_{\alpha}$ is maximal in $T$, and so $T=\left\langle T_{\alpha}, T_{\beta}\right\rangle$. Thus $\left|T_{\beta}: T_{\alpha \beta}\right|>2$ as $T$ is simple; in particular, $\operatorname{PSL}(2, p) \neq T_{\alpha \beta}$. Checking the subgroups of $T_{\alpha}$ which do not contain $\operatorname{PSL}(2, p)$ (refer to [3]), we conclude that $\left|T_{\alpha}: T_{\alpha \beta}\right|$ is divisible by $p$ or $p+1$. Thus part (i) occurs.

In the following, we assume that $T_{\alpha}$ is soluble. Since $p^{2}$ is not a divisor of $\left|T: T_{\alpha}\right|$, each Sylow $p$-subgroup of $T_{\alpha}$ has $p^{f}$ or $p^{f-1}$. Then, inspecting the subgroups of $T$, we conclude that $T_{\alpha} \cong T_{\beta}$ for $\beta \in \Gamma(\alpha)$, and that $T_{\alpha}$ has a unique Sylow $p$-subgroup.

Let $Q$ be a Sylow $p$-subgroup of $T_{\alpha \beta}$. Then $Q$ is normal in $T_{\alpha \beta}$. Suppose that $Q \neq 1$. Let $P_{1}$ and $P_{2}$ be the Sylow $p$-subgroups of $T_{\alpha}$ and $T_{\beta}$, respectively. Then $P_{1} \cap P_{2}=Q \neq 1$. By [11, II.8.5], any two distinct Sylow $p$-subgroups of $T$ intersect trivially. It follows $P_{1}$
and $P_{2}$ are contained the same Sylow $p$-subgroup, say $P$ of $T$. In particular, $P_{1}=P_{\alpha}$ and $P_{2}=P_{\beta}$. For $\gamma \in \Gamma(\beta)$, since $\Gamma$ is $G$-edge-transitive, we have $\left|T_{\alpha \beta}\right|=\left|T_{\beta \gamma}\right|$. A similar argument implies that $P_{\gamma}$ is the Sylow $p$-subgroup of $T_{\gamma}$. It follows from the connectedness of $\Gamma$ that $P_{\delta}$ is the Sylow $p$-subgroup of $T_{\delta}$ for any $\delta \in V$. Thus $P$ contains a normal subgroup $\left\langle P_{\delta} \mid \delta \in V\right\rangle \neq 1$ of $G$, a contradiction. Thus, $T_{\alpha \beta}$ is of order coprime to $p$, and so $\left|T_{\alpha}: T_{\alpha \beta}\right|$ is divisible by $\left|P_{1}\right|=p^{f-1}$ or $p^{f}$. Thus, by Lemma $9, k$ is divisible by $p^{f-1}$ or $p^{f}$, respectively.

If $M=\operatorname{PGL}(2, p)$ then, inspecting the subgroups of $M$, we conclude that $T_{\alpha}=\mathbb{Z}_{p}: \mathbb{Z}_{l}$, where $l$ is a divisor of $p-1$ and divisible by 4 . Assume that $M=\mathbb{Z}_{p}^{f}: \mathbb{Z}_{\frac{p^{f}-1}{(2, p-1)}}$. Then $T_{\alpha}=\mathbb{Z}_{p}^{f}: \mathbb{Z}_{l}$ or $\mathbb{Z}_{p}^{f-1}: \mathbb{Z}_{l}$ with $l$ dividing $\frac{p^{f}-1}{(2, p-1)}$. Suppose that $T_{\alpha}=\mathbb{Z}_{p}^{f-1}: \mathbb{Z}_{l}$. Noting that $M$ is a Frobenius group, $T_{\alpha}$ is also a Frobenius group. It follows that $l$ is a divisor of $p^{f-1}-1$, and so $l$ divides $p-1$.

Assume further that $\Gamma$ is $G$-locally primitive. Then $T_{\alpha}^{\Gamma(\alpha)}$ is a normal transitive soluble subgroup of the primitive permutation group $G_{\alpha}^{\Gamma(\alpha)}$ of degree $k$. Since $k$ is divisible by $\left|P_{1}\right|$, we have $\operatorname{soc}\left(G_{\alpha}^{\Gamma(\alpha)}\right) \cong \mathbb{Z}_{p}^{t}$ for some integer $t \geqslant 1$ such that $k=p^{t} \geqslant\left|P_{1}\right|$. It follows $T_{\alpha}^{\Gamma(\alpha)} \cong \mathbb{Z}_{p}^{t}: \mathbb{Z}_{l^{\prime}}$, where $l^{\prime}$ is a divisor of $l$. Since $P_{1}$ is the Sylow $p$-subgroup of $T_{\alpha}$, we have $p^{t} \leqslant\left|P_{1}\right|$. Then $k=\left|P_{1}\right|=p^{f-1}$ or $p^{f}$. Thus one of (ii) and (iii) follows.

The following lemma gives a characterization of graphs admitting Suzuki groups.
Lemma 15. Let $\Gamma=(V, E)$ be a connected $G$-edge-transitive graph of square-free order and valency $k$. Assume that $\operatorname{soc}(G)=\mathrm{Sz}\left(2^{f}\right)$ with odd $f \geqslant 3$, and that $\operatorname{soc}(G)$ has at most two orbits on $V$. Then $k$ is divisible by $2^{2 f-1}$ and $\Gamma$ is not $G$-locally primitive.

Proof. Let $\alpha \in V$ and $\beta \in \Gamma(\alpha)$. Since $\left|T: T_{\alpha}\right|$ is square-free, 4 does not divide $\left|T: T_{\alpha}\right|$, and hence $2^{2 f-1}$ divides $\left|T_{\alpha}\right|$. Then, inspecting the subgroups of $T$ (see [20]), we get $T_{\alpha}=\left[2^{n}\right]: \mathbb{Z}_{l}$, where $n=2 f$ or $2 f-1$, and $l$ is a divisor of $2^{f}-1$. So $T_{\alpha}$ has a unique Sylow 2-subgroup. By [20], for a Sylow 2-subgroup $Q$ of $T$, all involutions of $Q$ are contained in the center of $Q$. Noting that any two distinct conjugations of $Q$ generate $T$, it follows any two distinct Sylow 2-subgroups of $T$ intersect trivially. Thus, by a similar argument as in the above lemma, we know that $T_{\alpha \beta}$ has odd order. Thus $k=|\Gamma(\alpha)|$ is divisible by $n=2^{2 f}$ or $2^{2 f-1}$.

Finally, suppose that $G_{\alpha}^{\Gamma(\alpha)}$ is a primitive group. Let $Q_{1}$ be the Sylow 2-subgroup of $T_{\alpha}$, and $Q$ be a Sylow 2-subgroup of $T=\operatorname{Sz}\left(2^{f}\right)$ with $Q \geqslant Q_{1}$. Then $Q=Q_{1}$ or $Q_{1} \cdot \mathbb{Z}_{2}$. By a similar argument as in the above lemma, we conclude that $Q_{1}$ is isomorphic to $\operatorname{soc}\left(G_{\alpha}^{\Gamma(\alpha)}\right)$. It follows that $Q_{1}$ is an elementary abelian 2-group. By [20], $Q_{1}$ lies in the center of $Q$, and so $Q$ is abelian, which is impossible. Then this lemma follows.

## 5 Proof of Theorem 1

Let $\Gamma=(V, E)$ be a connected graph of square-free order and valency $k$. Assume that a subgroup $G \leqslant$ Aut $\Gamma$ acts transitively on $E$ and that each non-trivial normal subgroup of $G$ has at most 2 orbits on $V$. By Lemma 13, to complete the proof of the theorem, we
may assume that $G$ is almost simple. Let $T=\operatorname{soc}(G)$ and $\alpha \in V$. Then $T$ is transitive or has exactly two orbits on $V$, and every prime divisor of $\left|T_{\alpha}\right|$ is at most $k$.

Let $U$ be a $T$-orbit, and let $\mathcal{B}$ be a $T$-invariant partition on $U$ such that $|\mathcal{B}| \geqslant 2$ and $T^{\mathcal{B}}$ is primitive. Noting that $|\mathcal{B}|$ is square-free, $T$ is listed in [15, Tables 1-4]. In particular, if $T$ is one of sporadic simple groups then part (3) of Theorem 1 follows.

Assume that $T=\mathrm{A}_{n}$, where $n \geqslant 5$. Suppose that $n \geqslant 3 k$. By [15], there exists a prime $p$ such that $k<p<3 k / 2$, and thus $p^{2}$ divides $|T|$, and $p$ divides $\left|T_{\alpha}\right|$. So $p \leqslant k$, which is a contradiction. Therefore, $n<3 k$, as in part (4) of Theorem 1.

We next deal with the classical groups and the exceptional groups of Lie type. If $T=\operatorname{PSL}\left(2, p^{f}\right)$ or $\mathrm{Sz}\left(2^{f}\right)$ then, by Lemmas 14 and 15 , one of parts (5), (6) and (7) of Theorem 1 follows. Thus the following two lemmas will fulfill the proof of Theorem 1.
Lemma 16. Let $T$ be a d-dimensional classical simple group of Lie type over $\mathrm{GF}\left(p^{f}\right)$, where $p$ is a prime. Then either $T=\mathrm{PSL}(2, p)$, or $p \leqslant k$ and one of the following holds:
(i) $T=\operatorname{PSL}\left(2, p^{f}\right)$ with $f \geqslant 2$;
(ii) $\left[\frac{d}{2}\right] f<k$; if further $T=\operatorname{PSU}\left(d, p^{f}\right)$ then $2\left[\frac{d}{2}\right] f<k$ and $\left[\frac{d}{2}\right]$ is odd.

Proof. Let $\alpha \in V$. Then $\left|T: T_{\alpha}\right|$ is square-free and, by Lemma 6, each prime divisor of $\left|T_{\alpha}\right|$ is at most $k$. Assume that $T \neq \operatorname{PSL}(2, p)$. Let $P$ be a Sylow $p$-subgroup of $T$. Then $p^{2}$ divides $|P|$. Since $\left|T: T_{\alpha}\right|$ is square-free, $p$ divides $\left|T_{\alpha}\right|$, and so $p \leqslant k$.

Assume that $d \geqslant 3$. Let $d_{0}=\left[\frac{d}{2}\right]$, the largest integer no more than $\frac{d}{2}$. Check the orders of classical simple groups of Lie type, see [2, Section 47] for example. We conclude that either
(1) $\left(p^{2 d_{0} f}-1\right)\left(p^{d_{0} f}-1\right)$ divides $\left(d, p^{f}-1\right)|T|$; or
(2) $T=\operatorname{PSU}\left(d, p^{f}\right)$ with $d_{0}$ odd, and $\left(p^{2 d_{0} f}-1\right)\left(p^{d_{0} f}+1\right)$ divides $\left(d, p^{f}+1\right)|T|$.

Consider part (1) first. Suppose that $p^{d_{0} f}-1$ has a primitive prime divisor $r$. Then $r>d_{0} f$, and hence either $r=d=3$ and $f=1$, or $r^{2}$ divides $|T|$. For the former, $T=\operatorname{PSL}(3, p)$, and so $\left[\frac{d}{2}\right] f=1<k$. For the latter, $r$ divides $\left|T_{\alpha}\right|$, and so $d_{0} f<r \leqslant k$. Suppose that $p^{d_{0} f}-1$ has no primitive prime divisor. By Theorem 10, either $d_{0} f=2$ and $p+1$ is a power of 2 , or $\left(p, d_{0} f\right)=(2,6)$. For the former, $\left[\frac{d}{2}\right] f=d_{0} f=2<k$. Assume that $\left(p, d_{0} f\right)=(2,6)$. Then $\left(d_{0}, f\right)=(1,6),(2,3),(3,2)$, or $(6,1)$. It follows that $(d, f)=(3,6),(4,3),(5,3),(6,2),(7,2),(12,1)$ or $(13,1)$. Thus $|T|$ is divisible by $7^{2}$, and so $\left|T_{\alpha}\right|$ is divisible by 7 . Then $\left[\frac{d}{2}\right] f=d_{0} f=6<7 \leqslant k$ by Lemma 6 .

Now assume that $T=\operatorname{PSU}\left(d, p^{f}\right)$ with $d_{0}=\left[\frac{d}{2}\right]$ odd. Then $\left(p^{2 d_{0} f}-1\right)\left(p^{d_{0} f}+1\right)$ divides $\left(d, p^{f}+1\right)|T|$. A similar argument shows that either $p^{2 d_{0} f}-1$ has no primitive prime divisor, or $2 d_{0} f<k$. Assume that $p^{2 d_{0} f}-1$ has no primitive prime divisor. Then either $2 d_{0} f=2$, or $\left(p, 2 d_{0} f\right)=(2,6)$. For the former, $2 d_{0} f=2<k$. Suppose that $\left(p, 2 d_{0} f\right)=(2,6)$. Then $d_{0} f=3$, and so $\left(d, p^{f}\right)=\left(3,2^{3}\right),(6,2)$ or $(7,2)$. Thus $|T|$ is divisible by $7^{2}$, and so $2 d_{0} f=6<7 \leqslant k$.

Finally we consider the exceptional simple groups of Lie type.

Lemma 17. Let $T$ be an exceptional simple group of Lie type defined over $\mathrm{GF}\left(p^{f}\right)$ with $p$ prime. Then $p \leqslant k$, and one of the following holds:
(i) $T=\mathrm{Sz}\left(2^{f}\right)$;
(ii) $T=\mathrm{G}_{2}\left(p^{f}\right)$ or ${ }^{3} \mathrm{D}_{4}\left(p^{f}\right), p^{f} \neq 2^{3}$ and $2 f<k$;
(iii) $T=\mathrm{F}_{4}\left(p^{f}\right),{ }^{2} \mathrm{E}_{6}\left(p^{f}\right)$ or $\mathrm{E}_{7}\left(p^{f}\right), p^{f} \neq 2$ and $6 f<k$.

Proof. Note that $T$ has order divisible by $p^{2}$. Then $p$ divides $\left|T_{\alpha}\right|$, and so $p \leqslant k$. By [15, Table 4], $T$ is one of $\mathrm{Sz}\left(2^{f}\right), \mathrm{G}_{2}\left(p^{f}\right),{ }^{3} \mathrm{D}_{4}\left(p^{f}\right), \mathrm{F}_{4}\left(p^{f}\right),{ }^{2} \mathrm{E}_{6}\left(p^{f}\right)$ and $\mathrm{E}_{7}\left(p^{f}\right)$.

For $T=\mathrm{G}_{2}\left(p^{f}\right)$ or ${ }^{3} \mathrm{D}_{4}\left(p^{f}\right)$, the order $|T|$ is divisible by $\left(p^{f}+1\right)^{2}$ and $\left|T: T_{\alpha}\right|$ is divisible by $p^{f}+1$. If $p^{2 f}-1$ has a primitive prime divisor $r$, then $|T|$ is divisible by $r^{2}$, and $\left|T_{\alpha}\right|$ is divisible by $r$, hence $2 f<r \leqslant m$. Assume that $p^{2 f}-1$ has no primitive prime divisor. Then either $f=1$ and $2 f=2<k$, or $(p, 2 f)=(2,6)$. For the latter, $T=\mathrm{G}_{2}(8)$ or ${ }^{3} \mathrm{D}_{4}(8)$, and so 9 is a divisor of $\left|T: T_{\alpha}\right|$, which contradicts that $\left|T: T_{\alpha}\right|$ is square-free. Thus $T$ is described as in part (ii) of this lemma.

Assume that $T$ is one of $\mathrm{F}_{4}\left(p^{f}\right),{ }^{2} \mathrm{E}_{6}\left(p^{f}\right)$ and $\mathrm{E}_{7}\left(p^{f}\right)$. Then $|T|$ is divisible by $\left(p^{6 f}-1\right)^{2}$ and $\left|T: T_{\alpha}\right|$ is divisible by $\frac{p^{6 f}-1}{p^{f}-1}$. If $p^{6 f}-1$ has a primitive divisor $r$ say, then $r$ divides $\left|T_{\alpha}\right|$, and hence $6 f<r \leqslant k$. If $p^{6 f}-1$ has no primitive prime divisor, then $p=2$ and $f=1$, and so $\left|T: T_{\alpha}\right|$ is not square-free as it is divisible by 9 , and hence $T$ is described as in part(iii) of this lemma.

## 6 Graphs associated with $\operatorname{PSL}(2, p)$

In this section, we investigate vertex- and edge-transitive graphs associated with $\operatorname{PSL}(2, p)$, and then give a characterization for such graphs.

### 6.1 Examples

It is well-known that vertex- and edge-transitive graphs can be described as coset graphs. Let $G$ be a finite group and $H$ be a core-free subgroup of $G$, where core-free means that $\cap_{g \in G} H^{g}=1$. Let $[G: H]=\{H x \mid x \in G\}$, the set of right cosets of $H$ in $G$. For an element $g \in G \backslash H$, define the coset graph $\Gamma:=\operatorname{Cos}\left(G, H, H\left\{g, g^{-1}\right\} H\right)$ on $[G: H]$ such that ( $H x, H y$ ) is an arc of $\Gamma$ if and only if $y x^{-1} \in H\left\{g, g^{-1}\right\} H$. Then $\Gamma$ is a well-defined regular graph, and $G$ induces a subgroup of Aut $\Gamma$ acting on $[G: H]$ by right multiplication. The next lemma collects several basic facts on coset graphs.

Lemma 18. Let $G$ be a finite group and $H$ a core-free subgroup of $G$. Take $g \in G \backslash H$ and set $\Gamma=\operatorname{Cos}\left(G, H, H\left\{g, g^{-1}\right\} H\right)$. Then $\Gamma$ is $G$-vertex-transitive and $G$-edge-transitive. Moreover,
(1) $\Gamma$ is $G$-arc-transitive if and only if $H\left\{g, g^{-1}\right\} H=H x H$ for some 2-element $x \in$ $\mathbf{N}_{G}\left(H \cap H^{g}\right) \backslash H$ with $x^{2} \in H \cap H^{g}$;
(2) $\Gamma$ is connected if and only if $\langle H, g\rangle=G$.

Now we construct several examples.
Example 19. Let $T=\operatorname{PSL}(2, p), \mathbb{Z}_{p}: \mathbb{Z}_{l} \cong H<T$ and $\mathbb{Z}_{l} \cong K<H$, where $l$ is an even divisor of $\frac{p-1}{2}$ with $\frac{p-1}{2 l}$ odd. Then $\mathbf{N}_{T}(K) \cong \mathrm{D}_{p-1}$. Set $\mathbf{N}_{T}(K)=\langle a\rangle:\langle b\rangle$. It is easily shown that $\langle b, H\rangle=T$. Then $\operatorname{Cos}(T, H, H b H)$ is a connected $T$-arc-transitive graph of valency $p$.

Example 20. Let $T=\operatorname{PSL}(2, p)$ and $H$ a dihedral subgroup of $T$.
(1) Let $\mathbb{Z}_{2} \cong K<H \cong \mathrm{D}_{2 r}$ for an odd prime $r$ such that $|T: H|$ is square-free. Let $\epsilon= \pm 1$ such that 4 divides $p+\epsilon$. Then $\mathbf{N}_{T}(K)=K \times\langle a\rangle:\langle b\rangle \cong \mathbb{Z}_{2} \times \mathrm{D}_{\frac{p+\epsilon}{}} \cong \mathrm{D}_{p+\epsilon}$, where $b$ is an involution and, if $r$ divides $p+\epsilon$, we may choose $b$ such that $b$ centralizes $H$. Then, for $1 \leqslant i<\frac{p+\epsilon}{2}$, the coset graph $\operatorname{Cos}\left(T, H, H a^{i} b H\right)$ is a connected $T$-arctransitive graph of valency $r$.
(2) Let $G=T$ or $\operatorname{PGL}(2, p)$ and $\mathbb{Z}_{2}^{2} \cong K<H \cong \mathrm{D}_{4 r}$ for an odd prime $r$ with $|G: H|$ square-free. Suppose that $G$ contains a subgroup isomorphic to $\mathrm{S}_{4}$. Then $\mathbf{N}_{G}(K)=$ $K:\langle y, z\rangle \cong \mathrm{S}_{4}$, where $z$ is an involution with $y^{z}=y^{-1}$. Then $\operatorname{Cos}\left(G, T_{\alpha}, T_{\alpha} y z T_{\alpha}\right)$ is a $G$-arc-transitive graph of valency $r$.

Example 21. Let $\mathrm{A}_{4} \cong H<T=\operatorname{PSL}(2, p)<G=\operatorname{PGL}(2, p)$ with $|T: H|$ squarefree and $\mathbb{Z}_{3} \cong K<H$. Let $\epsilon= \pm 1$ with 3 dividing $p+\epsilon$. Then $\mathbf{N}_{T}(K) \cong \mathrm{D}_{p+\epsilon}$ and $\mathbf{N}_{G}(K) \cong \mathrm{D}_{2(p+\epsilon)}$. Moreover,
(1) $\operatorname{Cos}(T, H, H x H)$ is a connected $(T, 2)$-arc-transitive graph of valency 4 , where $x \in$ $\mathbf{N}_{T}(K) \backslash \mathbf{N}_{T}(H)$ is an involution;
(2) $\operatorname{Cos}(G, H, H x H)$ is a connected $(G, 2)$-arc-transitive graph of valency 4, where $x \in$ $\mathbf{N}_{G}(K) \backslash\left(T \cup \mathbf{N}_{G}(H)\right)$ is an involution.

Example 22. Let $\mathrm{S}_{4} \cong H<T=\operatorname{PSL}(2, p)$ with $|T: H|$ square-free.
(1) Let $\mathrm{D}_{8} \cong K<H$, and $X=T$ or $\operatorname{PGL}(2, p)$ such that $|X: H|$ is square-free and $X$ has a Sylow 2-subgroup isomorphic to $\mathrm{D}_{16}$. Then $\mathrm{D}_{16} \cong \mathbf{N}_{X}(K)=K:\langle z\rangle$ for an involution $z \in X \backslash H$, and $\operatorname{Cos}(X, H, H z H)$ is a connected ( $X, 2$ )-arc-transitive graph of valency 3 .
(2) Let $\mathrm{S}_{3} \cong K<H$ and $G=\operatorname{PGL}(2, p)$, and $\epsilon= \pm 1$ with 3 dividing $p+\epsilon$. Then $\mathbf{N}_{G}(K)=\langle o\rangle \times K$ for an involution $o$. Set $X=\langle o, H\rangle$. Then $X=T$ or $\operatorname{PGL}(2, p)$ depending on whether or not 12 divides $p+\epsilon$. Thus $\operatorname{Cos}(X, H, H o H)$ is a connected $(X, 2)$-arc-transitive graph of valency 4 .

Example 23. Let $\mathrm{A}_{5} \cong H<T=\operatorname{PSL}(2, p)<G=\operatorname{PGL}(2, p)$ and $K<H$ with $K \cong \mathrm{~A}_{4}$, $\mathrm{D}_{10}$ or $\mathrm{S}_{3}$. Then $\mathbf{N}_{G}(K)=K:\langle z\rangle \cong \mathrm{S}_{4}, \mathrm{D}_{20}$ or $\mathrm{D}_{12}$, respectively, where $z \in G \backslash H$ is an involution. Set $X=\langle z, H\rangle$. Then $X=T$ or $\operatorname{PGL}(2, p)$, and $\operatorname{Cos}(X, H, H z H)$ is either a connected ( $X, 2$ )-arc-transitive graph of valency 5 or 6 , or a connected $X$-locally primitive graph of valency 10 .

### 6.2 A characterization

Let $\Gamma=(V, E)$ be a connected $G$-edge-transitive graph of square-free order and valency $k \geqslant 3$, where $G \leqslant \operatorname{Aut} \Gamma$. Assume that $T:=\operatorname{soc}(G)=\operatorname{PSL}(2, p)$ for a prime $p \geqslant 5$, and that $G$ acts transitively on $V$.

Let $\alpha \in V$. Then $\left|T: T_{\alpha}\right|$ is square-free; in particular, $T_{\alpha}$ has even order. Since $|G: T| \leqslant 2$, either $T$ is transitive on $V$, or $T$ has two orbits on $V$ of the same length $\frac{|V|}{2}$. Thus $|V|=\left|T: T_{\alpha}\right|$ or $2\left|T: T_{\alpha}\right|$.

Note that the subgroups of $T$ are known, refer to [11, II.8.27]. We next analyze one by one the possible candidates for $T_{\alpha}$.

Lemma 24. Assume that $T_{\alpha}$ is cyclic. Then $T_{\alpha} \cong \mathbb{Z}_{m}$ for an even divisor $m$ of $\frac{p \pm 1}{2}, T$ is transitive on $V, \Gamma$ is not $G$-locally-primitive, and one of the following holds:
(i) $\Gamma$ is $T$-edge-transitive, and $k=m$ or $2 m$;
(ii) $G=\mathrm{PGL}(2, p), G_{\alpha} \cong \mathbb{Z}_{2 m}$ or $\mathrm{D}_{2 m}$, and $k=2 m$ or $4 m$.

Proof. Note $T_{\alpha}$ is a cyclic group of even order. By Lemma $7, T_{\alpha}$ is faithful and semiregular on $\Gamma(\alpha)$. It is easy to check that no primitive group contains a normal semiregular cyclic subgroup of even order. Thus $\Gamma$ is not $G$-locally-primitive. By [11, II.8.5], $T_{\alpha}$ is contained in a subgroup conjugate to $\mathbb{Z}_{\frac{p \pm 1}{2}}$ in $T$. Thus $T_{\alpha} \cong \mathbb{Z}_{m}$ for an even divisor $m$ of $\frac{p \pm 1}{2}$. Then $p(p \mp 1)$ is a divisor of $\left|T: T_{\alpha}\right|^{2}$, and so $\left|T: T_{\alpha}\right|$ is even. It follows that $T$ is transitive on $V$. Note that $\left|G_{\alpha}\right|=m$ or $2 m$. It follows that $\Gamma$ has valency $m, 2 m$ or $4 m$. Then (i) or (ii) is associated with the case that $T$ is transitive or intransitive on $E$, respectively.

Lemma 25. Assume that $\left|T_{\alpha}\right|$ is divisible by $p$. Then $T_{\alpha} \cong \mathbb{Z}_{p}: \mathbb{Z}_{l}, T$ is transitive on $V$ and $\Gamma$ has valency divisible by $p$, where $l$ is an even divisor of $\frac{p-1}{2}$ with $\frac{p-1}{2 l}$ odd. If $\Gamma$ is $G$-locally primitive, then $\Gamma$ is isomorphic to the graph in Example 19.

Proof. By [11, II.8.27], recalling that $T_{\alpha}$ has even order, $T_{\alpha} \cong \mathbb{Z}_{p}: \mathbb{Z}_{l}$ for an even divisor $l$ of $\frac{p-1}{2}$. Since $\left|T: T_{\alpha}\right|=\frac{p^{2}-1}{2 l}=(p+1) \frac{p-1}{2 l}$ is even and square-free, $\frac{p-1}{2 l}$ is odd and $T$ is transitive on $V$. By Lemma 7 , noting that $T_{\alpha}$ is a Frobenius group, $T_{\alpha}$ acts faithfully on $\Gamma(\alpha)$. In particular, each $T_{\alpha}$-orbit on $\Gamma(\alpha)$ has size divisible by $p$.

Assume that $\Gamma$ is $G$-locally primitive. Then $T_{\alpha}$ is transitive on $\Gamma(\alpha)$ as $T_{\alpha} \triangleleft G_{\alpha}$. It implies that $\Gamma$ has valency $p$ and $\Gamma$ is $T$-arc-transitive. Then $\Gamma \cong \operatorname{Cos}\left(T, T_{\alpha}, T_{\alpha} x T_{\alpha}\right)$ for some $x \in \mathbf{N}_{T}\left(T_{\alpha \beta}\right)$ with $x^{2} \in T_{\alpha \beta}$ and $\left\langle x, T_{\alpha}\right\rangle=T$, where $\beta \in \Gamma(\alpha)$. Note that $\mathbf{N}_{T}\left(T_{\alpha \beta}\right) \cong \mathrm{D}_{p-1}$. We write $\mathbf{N}_{T}\left(T_{\alpha \beta}\right)=\langle a\rangle:\langle b\rangle$. Let $M$ be a maximal subgroup of $T$ with $T_{\alpha} \leqslant M \cong \mathbb{Z}_{p}: \mathbb{Z}_{\frac{p-1}{2}}$. Then $\mathbb{Z}_{\frac{p-1}{2}} \cong \mathbf{N}_{M}\left(T_{\alpha \beta}\right) \leqslant \mathbf{N}_{T}\left(T_{\alpha \beta}\right)$. Thus $a \in M$. Write $\frac{p-1}{2}=i j$, where $i$ is odd and $j$ is a power of 2 . Then $\langle a\rangle=\left\langle a^{i}\right\rangle \times\left\langle a^{j}\right\rangle$. Since $T_{\alpha \beta} \cong \mathbb{Z}_{l}$ and $\frac{p-1}{2 l}$ is odd, we have $a^{i} \in T_{\alpha \beta} \leqslant T_{\alpha}$. Since $l$ is even, $j \neq 1$. It follows from $\left\langle x, T_{\alpha}\right\rangle=T$ that $x=a^{s i} a^{t j} b$ for some $s$ and $t$. Then $T_{\alpha} x T_{\alpha}=T_{\alpha} a^{t j} b T_{\alpha}=\left(T_{\alpha} b T_{\alpha}\right)^{-\frac{t j}{2}}$. Noting that $a^{-\frac{t j}{2}}$ normalizes $T_{\alpha}$, we have $\Gamma \cong \operatorname{Cos}\left(T, T_{\alpha}, T_{\alpha} x T_{\alpha}\right) \cong \operatorname{Cos}\left(T, T_{\alpha}, T_{\alpha} b T_{\alpha}\right)$ as constructed in Example 19.

Lemma 26. Assume that $T_{\alpha} \cong \mathrm{D}_{2 m}$ with $m>1$ coprime to $p$. Then $m$ is a divisor of $\frac{p \pm 1}{2}$, and $\Gamma$ has valency divisible by $\frac{m}{2}$ or $m$. If $\Gamma$ is $G$-locally-primitive, then $\Gamma$ has odd prime valency $r, T_{\alpha} \cong \mathrm{D}_{2 r}$ or $\mathrm{D}_{4 r}$, and $\Gamma$ is isomorphic to one of the graphs given in Example 20.

Proof. The first part follows from that $\left|T_{\alpha}\right|$ is a divisor of $|T|=\frac{p\left(p^{2}-1\right)}{2}$.
Let $\{\alpha, \beta\}$ be an edge of $\Gamma$. Suppose that $T_{\alpha \beta}$ contains a cyclic subgroup $C$ of order no less than 3. Then $C$ is the unique subgroup of order $|C|$ in both $T_{\alpha}$ and $T_{\beta}$. For an arbitrary edge $\{\gamma, \delta\}$, since $\Gamma$ is $G$-edge-transitive, $\{\gamma, \delta\}=\{\alpha, \beta\}^{x}$ for $x \in G$, so $T_{\gamma \delta}=T_{\alpha^{x} \beta^{x}}=T \cap G_{\alpha^{x} \beta^{x}}=T \cap\left(G_{\alpha \beta}\right)^{x}=\left(T_{\alpha \beta}\right)^{x}$. Then $C^{x}$ is the unique subgroup of order $|C|$ in both $T_{\gamma}$ and $T_{\delta}$. So $C \leqslant T_{\gamma}$ for $\gamma \in \Gamma(\alpha) \cup \Gamma(\beta)$. Since $\Gamma$ is connected, $C$ fixes each vertex of $\Gamma$, and so $C=1$ as $C \leqslant \operatorname{Aut} \Gamma$, a contradiction. Thus $\left|T_{\alpha \beta}\right|$ is a divisor of 4 , and hence $\Gamma$ has valency divisible by $\frac{m}{2}$ or $m$.

Assume that $\Gamma$ is $G$-locally primitive. Then $T_{\alpha}^{\Gamma(\alpha)}$ contains a transitive normal cyclic subgroup. Thus $|\Gamma(\alpha)|=r$ is an odd prime, and $T_{\alpha}^{\Gamma(\alpha)} \cong T_{\alpha} / T_{\alpha}^{[1]} \cong\left(T_{\alpha} G_{\alpha}^{[1]}\right) / G_{\alpha}^{[1]} \cong \mathrm{D}_{2 r}$. Note that $T_{\alpha}^{[1]}$ is a normal cyclic subgroup of $T_{\alpha}$. By the argument in above paragraph, $\left|T_{\alpha}^{[1]}\right| \leqslant 2$. It follows that $T_{\alpha} \cong \mathrm{D}_{2 r}$ or $\mathrm{D}_{4 r}$.

Let $T_{\alpha} \cong \mathrm{D}_{2 r}$. Then $\left|T: T_{\alpha}\right|$ is even, so $T$ is transitive on $V$, and hence $\Gamma$ is $T$ -arc-transitive. Then $\Gamma \cong \operatorname{Cos}\left(T, T_{\alpha}, T_{\alpha} x T_{\alpha}\right)$ for some $x \in \mathbf{N}_{T}\left(T_{\alpha \beta}\right)$ with $x^{2} \in T_{\alpha \beta}$ and $\left\langle x, T_{\alpha}\right\rangle=T$. Let $\epsilon= \pm 1$ such that 4 divides $p+\epsilon$. Then $\mathbf{N}_{T}\left(T_{\alpha \beta}\right)=T_{\alpha \beta} \times\langle a\rangle:\langle b\rangle \cong$ $\mathbb{Z}_{2} \times \mathrm{D}_{\frac{p+\epsilon}{2}} \cong \mathrm{D}_{p+\epsilon}$. It implies that $x$ is an involution. If $r$ does not divides $p+\epsilon$, then $x=a^{i} b$ for some $1 \leqslant i \leqslant \frac{p+\epsilon}{2}$. Assume that $r$ is a divisor of $p+\epsilon$. Then $T_{\alpha}$ is contained in a maximal subgroup $M \cong \mathrm{D}_{p+\epsilon}$ of $T$, and $\mathbf{N}_{M}\left(T_{\alpha \beta}\right) \cong \mathbb{Z}_{2}^{2}$ contains the center of $M$. Without loss of generality, we choose $b$ in the center of $M$, and so $x=a^{i} b$ for $1 \leqslant i<\frac{p+\epsilon}{2}$. Thus $\Gamma$ is isomorphic to a graph given in Example 20 (1).

Now let $T_{\alpha} \cong \mathrm{D}_{4 r}$. Then $T_{\alpha \beta} \cong \mathbb{Z}_{2}^{2}$. If $T$ is not transitive on $V \Gamma$, then $G=\operatorname{PGL}(2, p)$, $\Gamma$ is a bipartite graph, and $T_{\alpha}=G_{\alpha}$. Thus we set $X=\operatorname{PSL}(2, p)$ or $\operatorname{PGL}(2, p)$ depending respectively on whether or not $T$ is is transitive on $V \Gamma$. Then $\Gamma \cong \operatorname{Cos}\left(X, T_{\alpha}, T_{\alpha} x T_{\alpha}\right)$ for some $x \in \mathbf{N}_{X}\left(T_{\alpha \beta}\right) \backslash T_{\alpha \beta}$ with $x^{2} \in T_{\alpha \beta}$; in particular, $\mathbf{N}_{X}\left(T_{\alpha \beta}\right) / T_{\alpha \beta}$ is of even order It implies that $\mathbf{N}_{T}\left(T_{\alpha \beta}\right) \cong \mathrm{S}_{4}$. Let $M$ be the maximal subgroup of $X$ with $T_{\alpha} \leqslant M$. Then 8 divides $|M|$, and $\mathbf{N}_{M}\left(T_{\alpha \beta}\right) \cong \mathrm{D}_{8}$. Take $\mathrm{D}_{8 r} \cong M_{1} \geqslant T_{\alpha}$. Then $\mathbf{N}_{M}\left(T_{\alpha \beta}\right)=$ $\mathbf{N}_{M_{1}}\left(T_{\alpha \beta}\right)$. We write $\mathbf{N}_{X}\left(T_{\alpha \beta}\right)=T_{\alpha \beta}:(\langle y\rangle:\langle z\rangle)$, where $z \in \mathbf{N}_{M}\left(T_{\alpha \beta}\right)$ and $\langle y\rangle:\langle z\rangle \cong \mathrm{S}_{3}$. Noting that $x \notin \mathbf{N}_{M}\left(T_{\alpha \beta}\right)$ and $x$ is of even order, we have $x=x_{1} y^{i} z$ for some $x_{1} \in T_{\alpha \beta}$ and $i=1$ or 2 . Noting that $z$ normalizes $T_{\alpha}$ and $y^{z}=y^{-1}$, we have $\operatorname{Cos}\left(X, T_{\alpha}, T_{\alpha} x T_{\alpha}\right)=$ $\operatorname{Cos}\left(X, T_{\alpha}, T_{\alpha} y^{i} z T_{\alpha}\right) \cong \operatorname{Cos}\left(X, T_{\alpha}, T_{\alpha} y z T_{\alpha}\right)$. Thus $\Gamma$ is isomorphic to the graph given in Example 20 (2).

Theorem 27. Let $\Gamma=(V, E)$ be a connected $G$-edge-transitive graph of square-free order and valency $k \geqslant 3$, where $G \leqslant \operatorname{Aut} \Gamma$. Assume that $\operatorname{soc}(G)=\operatorname{PSL}(2, p)$ for a prime $p \geqslant 5$, and that $G$ is transitive on $V$. Then, for $\alpha \in V$, the pair $\left(\operatorname{soc}(G)_{\alpha}, k\right)$ lies in Table 1. Further, if $\Gamma$ is $G$-locally primitive, then $\left(\operatorname{soc}(G)_{\alpha}, k\right)$ lies in Table 2.

Table 2:

Proof. Let $\Gamma=(V, E)$ be a connected $G$-edge-transitive graph of square-free order and valency $k \geqslant 3$, where $G \leqslant \operatorname{Aut} \Gamma$. Assume that $T:=\operatorname{soc}(G)=\operatorname{PSL}(2, p)$ for a prime $p \geqslant 5$, and that $G$ acts transitively on $V$. Let $\{\alpha, \beta\} \in E$.

Noting that $\left|G: G_{\alpha}\right|=\left|T: T_{\alpha}\right|$ or $2\left|T: T_{\alpha}\right|$, we have $\left|G_{\alpha}: T_{\alpha}\right|=1$ or 2 . Then $T_{\alpha}$ has at most two orbits on each $G_{\alpha}$-orbits on $\Gamma(\alpha)$. By Lemma 9 , we have $k=|\Gamma(\alpha)|=l, 2 l$ or $4 l$, where $l=\left|T_{\alpha}: T_{\alpha \beta}\right|$. By Lemmas 24, 25 and 26, we need only consider the remaining case: $T_{\alpha} \cong \mathrm{A}_{4}, \mathrm{~S}_{4}$ or $\mathrm{A}_{5}$.

Let $T_{\alpha} \cong \mathrm{S}_{4}$ or $\mathrm{A}_{5}$. Checking the maximal subgroups of PGL $(2, p)$ (see [3], for example), we know that PGL $(2, p)$ has no subgroups of order $2\left|T_{\alpha}\right|$. It follows that $G_{\alpha}=T_{\alpha}$. Then $k=l$ or $2 l$ depending whether or not $T_{\alpha}^{\Gamma(\alpha)}$ is transitive. If $T_{\alpha} \cong \mathrm{S}_{4}$, then $T_{\alpha}^{\Gamma(\alpha)} \cong \mathrm{S}_{3}$ or $\mathrm{S}_{4}$, which implies that $l \geqslant 3$ and $l$ divides 24 . If $T_{\alpha} \cong \mathrm{A}_{5}$, Then $l \geqslant 5$ is a divisor of 60 .

Let $T_{\alpha} \cong \mathrm{A}_{4}$. Assume that $T$ is transitive on $E$. Then $k=l$ or $2 l$, where $l=\left|T_{\alpha}: T_{\alpha \beta}\right|$ for $\alpha \in \Gamma(\alpha)$. By Lemma $7, l \neq 3$. Thus $l \in\{4,6,12\}$. Assume that $T$ is intransitive on $E$. Then $G=\operatorname{PGL}(2, p)$ and $G_{\alpha} \cong \mathrm{S}_{4}$, and hence $p \equiv \pm 3(\bmod 8)$ by checking the maximal subgroups of $G$. By Lemma 7 , we conclude that $T_{\alpha}^{\Gamma(\alpha)} \cong \mathrm{A}_{4}$ and $G_{\alpha}^{\Gamma(\alpha)} \cong \mathrm{S}_{4}$. It follows that $k=2 l$ or $4 l$ for $l \in\{4,6,12\}$.

Further, if $\Gamma$ is $G$-locally primitive, then $k=4$ for $T_{\alpha} \cong \mathrm{A}_{4}, k=3$ or 4 for $T_{\alpha} \cong \mathrm{S}_{4}$, and $k=5,6$ or 10 for $T_{\alpha} \cong \mathrm{A}_{5}$. Next we determine the $G$-locally primitive graphs.

Let $T_{\alpha} \cong \mathrm{A}_{4}$. Then $T_{\alpha \beta} \cong \mathbb{Z}_{3}$, and $\Gamma$ is $(G, 2)$-arc-transitive and of valency 4. Let $X=$ $T$ or PGL $(2, p)$ depending $T$ is transitive or intransitive on $V$. Then $\mathbf{N}_{X}\left(T_{\alpha \beta}\right) \cong \mathrm{D}_{t(p+\epsilon)}$, where $t=|X: T|$ and $\epsilon= \pm 1$ such that 3 divides $p+\epsilon$. Let $x \in \mathbf{N}_{X}\left(T_{\alpha \beta}\right)$ with $x^{2} \in T_{\alpha \beta}$ and $\left\langle x, T_{\alpha}\right\rangle=X$. Then $x$ is either an involution or of order 6 , and $x y$ is an involution

| $M$ | $T_{\alpha}$ | $k$ | $T$-orbits | remark |

Table 3:
for some $y \in T_{\alpha \beta}$. Note that $T_{\alpha} x T_{\alpha}=T_{\alpha} x y T_{\alpha}$. Thus, writing $\Gamma$ as a coset graph, $\Gamma$ is isomorphic to one of the graphs in Example 21.

Let $T_{\alpha} \cong \mathrm{S}_{4}$. Then $G_{\alpha}=T_{\alpha}$. If $\Gamma$ has valency 3 , then $\Gamma$ is isomorphic the graph given in Example 22 (1). If $\Gamma$ has valency 4, then $G_{\alpha \beta} \cong S_{3}$ and $\mathbf{N}_{G}\left(G_{\alpha \beta}\right)=\mathbb{Z}_{2} \times S_{3}$, it follows that $\Gamma$ is isomorphic the graph given in Example 22 (2).

Finally, if $T_{\alpha}=\mathrm{A}_{5}$ then $G_{\alpha}=T_{\alpha}$ and $G_{\alpha \beta} \cong \mathrm{A}_{4}, \mathrm{D}_{10}$ or $\mathrm{S}_{3}$, and thus $\Gamma$ is isomorphic one of the graphs given in Example 23.

## 7 Locally primitive arc-transitive graphs

In this section we give a proof of Theorem 4. We first prove a technical lemma.
Lemma 28. Let $G$ be a transitive permutation group on $V$ of square-free degree and let $M$ be a normal subgroup of $G$. Assume that $M$ is semiregular on $V$ and $G / M$ acts faithfully on the $M$-orbits. Then there is $X \leqslant G$ such that $G=M: X$.

Proof. The result is trivial if $M=1$. Thus we assume that $M \neq 1$. Note that $M$ has square-free order. Let $p$ be the largest prime divisor of $|M|$ and $P$ be the Sylow $p$-subgroup of $M$. Then $P$ is cyclic and is normal in $G$. Let $\alpha \in V$ and $B$ be the $P$-orbit with $\alpha \in B$. Let $V_{P}$ be the set of $P$-orbits. Then $|B|=p$ is coprime to $\left|V_{P}\right|$. Then $G_{B}=P: G_{\alpha}$ contains a Sylow $p$-subgroup $P \times Q$ of $G$, where $Q$ is a Sylow $p$-subgroup of $G_{\alpha}$. It follows from $[2,10.4]$ that the extension $G=P .(G / P)$ splits over $P$. Thus $G=P: H$ for some $H<G$ with $H \cap P=1$. If $M=P$, then the result follows. We assume $M \neq P$ in the following.

Let $K$ be the kernel of $G$ acting on $V_{P}$. Noting that each $M$-orbit on $V$ consists of several $P$-orbits, we know that $K$ fixes each $M$-orbits set-wise. It follows from the assumptions that $K \leqslant M$. Then, considering the action of $M$ on its an orbit, we conclude that $K=P$. Thus $H$ is faithful and transitive on $V_{P}$. Further, $M=M \cap P H=P(M \cap H)$
implies that $M \cap H$ is semiregular on $V_{P}$. It is easily shown that $H /(M \cap H)$ acts faithfully on the $(M \cap H)$-orbits on $V_{P}$. Noting that $\left|V_{P}\right|<|V|$, we may assume by induction that $H=(M \cap H) X$ with $X \cap(M \cap H)=1$. Then $G=P((M \cap H) X)=M X$, and $M \cap X \leqslant M \cap H$ yielding $M \cap X \leqslant M \cap H \cap X=1$, hence our result follows.

Let $\Gamma=(V, E)$ be a connected $G$-locally primitive graph. Suppose that $G$ has a normal subgroup $N$ which has at least three orbits on $V$. Then either the quotient graph $\Gamma_{N}$ is a star, or $\Gamma$ is a normal cover of $\Gamma_{N}$, refer to [10, Theorem 1.1]. Then following lemma is easily shown.

Lemma 29. Let $\Gamma=(V, E)$ be a connected $G$-locally primitive and $G$-symmetric graph. Let $N$ be a normal subgroup of $G$. If $N$ is not semiregular on $V$, then $N$ is transitive on $E$ and has at most two orbits on $V$.

Theorem 30. Let $\Gamma=(V, E)$ be a connected $G$-locally primitive graph of square-free order and valency $k>2$. Let $M \triangleleft G$ be maximal subject to that $M$ has at least three orbits on $V$. Assume further that $\Gamma_{M}$ is not a star. Then one of the following holds.
(1) $M=1, \Gamma$ and $G$ are described as in (1) or (5) of Lemma 13;
(2) $\Gamma$ is a bipartite graph, $G \cong \mathrm{D}_{2 n}: \mathbb{Z}_{k}, \mathbb{Z}_{n}: \mathbb{Z}_{k}$ or $\mathbb{Z}_{\frac{n}{k}}: \mathbb{Z}_{k}^{2}$, and $k$ is the smallest prime divisor of $n k$;
(3) $G=M: X, M \operatorname{soc}(X)=M \times \operatorname{soc}(X)$ and $\operatorname{soc}(X)$ is a simple group descried in (3)-(6) and (8) of Theorem 1.

Proof. Since $\Gamma_{M}$ is not a star, $\Gamma$ is a normal cover of $\Gamma_{M}$, hence $M$ is semiregular on $V$; in particular, $|M|$ is coprime to $\left|V_{M}\right|$. By the choice of $M$, we know that $G / M$ is faithful on either $V_{M}$ or one of two $G / M$-orbits on $V_{M}$. Then, by Lemma 28, we have $G=M: X$. Note that $\Gamma_{M}$ is $G / M$-locally primitive, and the pair $G / M$ and $\Gamma_{M}$ satisfies the assumptions in Theorem 1. Let $Y=\operatorname{soc}(X)$. Then, by Lemma $13, \Gamma_{M} \cong \mathrm{~K}_{k, k}$ and $Y \cong T^{2}$ for a simple group $T$, or $Y$ is a minimal normal subgroup of $X$.

Since $|M|$ is square-free, $M$ has soluble automorphism $\operatorname{group} \operatorname{Aut}(M)$. Noting that $G / \mathbf{C}_{G}(M)=\mathbf{N}_{G}(M) / \mathbf{C}_{G}(M) \lesssim \operatorname{Aut}(M)$, it follows that $G / \mathbf{C}_{G}(M)$ is soluble. If $Y$ is a nonabelian simple group then $Y \leqslant \mathbf{C}_{G}(M)$, and hence $M Y=M \times Y$, and so part (3) of this theorem occurs. We next complete the proof in two cases.

Case 1. $\Gamma_{M} \cong \mathrm{~K}_{k, k}$ and $Y \cong T^{2}$ for a simple group $T$. In this case, by Lemma $13, X$ is transitive on $V_{M}$, and so $\Gamma_{M}$ is $X$-arc-transitive. Then $\Gamma$ is $G$-arc-transitive. Moreover, $Y$ has exactly two orbits on $V_{M}$ of size $k$. Thus $M Y$ has exactly two orbits $U$ and $W$ on $V$ of length $k|M|$. Let $U_{M}$ and $W_{M}$ be the sets of $M$-orbits on $U$ and $W$, respectively. Then $U_{M}$ and $W_{M}$ are $Y$-orbits on $V_{M}$.

Assume first that $T$ is a nonabelian simple group. Then part (5) of Lemma 13 holds for the pair $\left(X, \Gamma_{M}\right)$. In particular, $Y$ is the unique minimal normal subgroup of $X$. Let $\Delta$ be an $M$-orbit on $V$. Suppose that $T \cong \mathrm{~A}_{7}$. Then $k=105$ and $T_{\Delta} \cong \mathrm{A}_{6} \times \operatorname{PSL}(3,2)$. It is easily shown that $\Gamma_{M}$ is not $X$-locally primitive, which is not the case. Thus $Y$ is unfaithful on both $U_{M}$ and $W_{M}$. Let $K$ be the kernel of $Y$ acting on $U_{M}$. Then $K \cong T$
and, $Y=K \times K^{x}$ for $x \in X \backslash Y$. It is easily shown that $K \cong T$ is transitive on $W_{M}$. Recalling that $G / \mathbf{C}_{G}(M)$ is soluble, it follows that $K \leqslant \mathbf{C}_{M K}(M)$ and so $M K=M \times K$. Considering the action of $M K$ on $\Delta$, we conclude that $K$ acts trivially on $\Delta$. Then $K$ acts trivially on $U$. Since $K$ is transitive on $W_{M}$, we conclude that $\Gamma \cong \mathrm{K}_{k, k}$. It follows that $M=1$, and so (1) of this theorem occurs.

Now let $T \cong \mathbb{Z}_{p}$ for an odd prime $p$. Then $k=p$ is coprime to $|M|$, and so $|V|=2 k|M|$. Noting that $\Gamma_{M}$ has odd valency $k$, it implies that $\Gamma_{M}$ has even order, and so $|M|$ is odd. Moreover, by Lemma $13, X \cong G / M \cong\left(\mathbb{Z}_{k}^{2}: \mathbb{Z}_{l}\right) \cdot \mathbb{Z}_{2}$ is nonabelian, where $l$ is a divisor of $k-1$. Since $|M|$ is square-free, $M$ is soluble, and so $G$ is soluble. Let $F$ be the Fitting subgroup of $G$. Then $\mathbf{C}_{G}(F) \leqslant F \neq 1$. Suppose that $F$ has at least three orbits on $V$. Since $\Gamma$ is $G$-locally primitive and $G$-vertex-transitive, $\Gamma$ is a normal cover of $\Gamma_{F}$; in particular, $F$ has square-free order. Then $G / F$ is isomorphic to a subgroup of Aut $\Gamma_{F}$ acting transitively on the arcs of $\Gamma_{F}$, and so $G / F$ is not abelian. On other hand, since $|F|$ is square-free, $F$ is cyclic, and hence $\mathbf{C}_{G}(F)=F$ and $\operatorname{Aut}(F)$ is abelian. Since $G / F=\mathbf{N}_{G}(F) / \mathbf{C}_{G}(F) \lesssim \operatorname{Aut}(F)$, we know that $G / F$ is abelian, a contradiction. Thus $F$ has one or two orbits on $V$. Suppose that $|F|$ is even. Let $Q$ be the Sylow 2-subgroup of $F$. Then $Q \triangleleft G$. Consider the quotient $\Gamma_{Q}$. Since $|V|$ is square-free and $\Gamma$ is $G$-vertextransitive, we get a graph of odd order $k|M|$ and odd valency $k$, which is impossible. Then $F$ has odd order, and hence $F$ has exactly two orbits on $V$.

Assume $|F|$ is divisible by $k^{2}$. Let $P$ be the Sylow $k$-subgroup of $F$. Then $\mathbb{Z}_{k}^{2} \cong Y=$ $\operatorname{soc}(X)=P \triangleleft G$. By Lemma 29, we conclude that $\Gamma \cong \mathrm{K}_{k, k}$. This implies that $M=1$, and $\Gamma$ and $G$ are described as in (1) of Lemma 13. Then (1) of this theorem occurs.

Assume that $|F|$ is not divisible by $k^{2}$. Then $M \neq 1$; otherwise $\mathbb{Z}_{k}^{2} \cong Y \leqslant F$, a contradiction. Since $F$ has exactly two orbits on $V$, we know that $|F|$ is divisible by $k|M|$. Let $P$ be the Sylow $k$-subgroup of $F$. Then $\mathbb{Z}_{k} \cong P \triangleleft G$. Let $q$ be the smallest prime divisor of $|M|$, and the let $N$ be the $q^{\prime}$-Hall subgroup of $M$. Then $N P$ is a normal subgroup of $G$. It is easy to see that $N P$ is intransitive on both $U$ and $W$. Then the quotient graph $\Gamma_{N P}$ is bipartite and of order $2 q$ and valency $k$, and so $q>k$. Thus, since $l$ is a divisor of $k-1$, each possible prime divisor of $l$ is less than $q$. Note that $F M$ is a subgroup of $G$. Then $|G|=2 l k^{2}|M|$ is divisible by $|F M|=\frac{|F||M|}{|F \cap M|}$. Recalling that $|F|$ is divisible by $k|M|$, it follows that $M \leqslant F$. Let $r$ be an arbitrary prime divisor of $|F|$, and let $R$ be the Sylow $r$-subgroup of $F$. Then $R \triangleleft G$ and $r$ is odd. Since $G$ is transitive on $V$, all $R$-orbits on $V$ have the same length. It implies that $r$ is a divisor of $|V|$, and so $r$ is a divisor of $k|M|$. The above argument yields that $|F|=k|M|$, and so $|F|$ is square-free. Then $F$ is cyclic and semiregular on $V, \mathbf{C}_{G}(F)=F$ and $\operatorname{Aut}(F)$ is abelian. Since $G_{\alpha} \cong G_{\alpha} F / F \leqslant G / F=\mathbf{N}_{G}(F) / \mathbf{C}_{G}(F) \lesssim \operatorname{Aut}(F)$, we know that both $G_{\alpha}$ and $G / F$ are abelian. By Lemma $8, G_{\alpha} \cong \mathbb{Z}_{k}$. Since $\left|G:\left(F G_{\alpha}\right)\right|=2$, we have $G=F \cdot \mathbb{Z}_{2 k}$. Thus $G$ has a normal regular subgroup $F: \mathbb{Z}_{2}$. Then $\Gamma$ is isomorphic a Cayley graph Cay $\left(F: \mathbb{Z}_{2}, S\right)$, where $S=\left\{s^{\tau^{i}} \mid 0 \leqslant i \leqslant k-1\right\}$ for an involution $s \in F: \mathbb{Z}_{2}$ and $\tau \in \operatorname{Aut}\left(F: \mathbb{Z}_{2}\right)$ of order $k$ such that $\langle S\rangle=F: \mathbb{Z}_{2}$. Noting that $\left|F: \mathbb{Z}_{2}\right|$ is square-free, it follows that $F: \mathbb{Z}_{2}$ is a dihedral group, say $\mathrm{D}_{2 n}$. Then part (2) of this theorem occurs.

Case 2. $\operatorname{soc}(G / M) \cong \operatorname{soc}(X)=Y \cong \mathbb{Z}_{p}$. Since $\Gamma_{M}$ is $X$-locally primitive, by Lemma 13, either $X \cong \mathbb{Z}_{p}: \mathbb{Z}_{k}$, or $X \cong \mathbb{Z}_{p}: \mathbb{Z}_{2 k}$ and $X$ is transitive on $V_{M}$. Moreover,
$\left|V_{M}\right|=2 p,(p,|M|)=1, p>k$ and $k$ is an odd prime. Let $L=M Y$. Then $L$ is a semiregular normal subgroup of $G$, and $L$ has exactly two orbits $U$ and $W$ on $V$.

Let $X \cong \mathbb{Z}_{p}: \mathbb{Z}_{k}$. Then $|G|=k p|M|=k|L|$. Assume that $|L|$ has a prime divisor $q$ such that either a Sylow $q$-subgroup of $L$ is not normal in $L$ or $q$ is the smallest prime divisor of $|L|$. It is easily shown that $L$ has a unique $q^{\prime}$-Hall subgroup $N$; in particular, $N$ is normal in $L$. Then $N$ is normal in $G$, and $N$ has $q$-orbits on each of $U$ and $W$. Thus the quotient graph $\Gamma_{N}$ is bipartite and of order $2 q$ and valency $k$. In particular, $k \leqslant q$. Further, $G / N=\mathbb{Z}_{q}: \mathbb{Z}_{k}$ is not abelain unless $q=k$. Since $|N|$ is square-free, the outer automorphism group $\operatorname{Out}(N)$ of $N$ is abelian, refer to [12]. Note that $G /\left(N \mathbf{C}_{G}(N)\right)$ is isomorphic a quotient of a subgroup of $\operatorname{Out}(N)$. Then $G /\left(N \mathbf{C}_{G}(N)\right)$ is abelian. Thus either $q=k$, or $N \mathbf{C}_{G}(N)$ has order divisible by $q$. Suppose that $q>k$. Then $q$ is not a divisor of $|N|$ as $N \leqslant L$ and $|L|$ is square-free. Note that $N \mathbf{C}_{G}(N) / N \cong \mathbf{C}_{G}(N) /\left(N \cap \mathbf{C}_{G}(N)\right)$. It follows that $\left|\mathbf{C}_{G}(N)\right|$ is divisible by $q$. Let $Q$ be a Sylow $q$-subgroup of $\mathbf{C}_{G}(N)$. Then $Q$ is also a Sylow $q$-subgroup of $G$, and hence $Q \leqslant L$. Moreover, $N Q / N \triangleleft G / N$, and so $N Q \triangleleft G$. Since $N Q=N \times Q$, we know that $Q \triangleleft G$, which contradicts the choice of $q$. Therefore, $q=k$. This says that $k$ is the smallest prime divisor of $|G|$, and either $L \cong \mathbb{Z}_{n}$ or $L \cong \mathbb{Z}_{\frac{n}{k}}: \mathbb{Z}_{k}$, where $n=|L|$. Thus $G=\mathbb{Z}_{n}: \mathbb{Z}_{k}$ or $\mathbb{Z}_{\frac{n}{k}}: \mathbb{Z}_{k}^{2}$, and $k$ is the smallest prime divisor of $n k$.

Now let $X \cong \mathbb{Z}_{p}: \mathbb{Z}_{2 k}$. Then $G$ has a normal regular subgroup $R=L: \mathbb{Z}_{2}$, and $\Gamma$ is isomorphic a Cayley graph $\operatorname{Cay}(R, S)$, where $S=\left\{s^{\tau^{i}} \mid 0 \leqslant i \leqslant k-1\right\}$ for an involution $s \in R$ and an automorphism $\tau \in \operatorname{Aut}(R)$ of order $k$ such that $\langle S\rangle=R$. Noting that $|R|$ is square-free, it follows that $R$ is a dihedral group, say $\mathrm{D}_{2 n}$. Then $G=\mathrm{D}_{2 n}: \mathbb{Z}_{k}$. Let $q$ be the smallest prime divisor of $n$. Then $G$ has a normal subgroup $N$ with $|G: N|=2 q k$. It is easily shown that the quotient graph $\Gamma_{N}$ is bipartite and of valency $k$ and order $2 q$. Then $k \leqslant q$, and so $k$ is the smallest prime divisor of $n k$. Thus part (2) follows.

Now we are ready to give a proof of Theorem 4.
Proof of Theorem 4. Let $\Gamma=(V, E)$ be a $G$-locally primitive arc-transitive graph, and let $M \triangleleft G$ be maximal subject to that $M$ has at least three orbits on $V$. Then $\Gamma$ is a normal cover of $\Sigma:=\Gamma_{M}$. Note that $\Gamma$ and $\Sigma$ has even valency if $|M|$ is even.

If $G$ is soluble then, by Theorem 30, one of part (1) of Theorem 4 occurs. Thus we assume that $G$ is insoluble. Then $G=M: X$, where $T:=\operatorname{soc}(X)$ is a simple group descried in (3)-(6) and (8) of Theorem 1. By Lemma 29, we conclude that either $\Gamma$ is $T$-arc-transitive, or $\Gamma$ is $T$-edge-transitive and $T$ has exactly two orbits on $V$. We next consider the case where $T=\operatorname{PSL}(2, p)$ for a prime $p \geqslant 5$.

Let $\Delta$ be an $M$-orbit on $V$. Then either $T_{\Delta}$ is transitive on $\Delta$; or $T_{\Delta}$ has exactly two orbits on $\Delta$ and, in this case, $T$ is intransitive on $V$ and $M \times T$ is transitive on $V$. We take a normal subgroup $N$ of $G$ such that $N=M$ if the first case occurs, or $N$ is the $2^{\prime}$-Hall subgroup of $M$ if the second case occurs. Let $\Delta_{1}$ be an $N$-orbit contained in $\Delta$. Then $T_{\Delta}=T_{\Delta_{1}}$ is transitive on $\Delta_{1}$ and $N$ is regular on $\Delta_{1}$. Considering the action of $N \times T_{\Delta}$, we conclude that $N \cong T_{\Delta} / K$, where $K$ is the kernel of $T_{\Delta}$ on $\Delta_{1}$. Note that $T_{\Delta}$ is known by Theorem 27, and that $|V|=\left|T: T_{\alpha}\right|$ or $2\left|T: T_{\alpha}\right|$ is square-free. Then we get Table 3 by checking possible normal subgroups of $T_{\Delta}$ with square-free index.
