Abstract

Babson and Steingrímsson introduced generalized permutation patterns and showed that most of the Mahonian statistics in the literature can be expressed by the combination of generalized pattern functions. Particularly, they defined a new Mahonian statistic in terms of generalized pattern functions, which is denoted \( \text{stat} \). Given a permutation \( \pi \), let \( \text{des}(\pi) \) denote the descent number of \( \pi \) and \( \text{maj}(\pi) \) denote the major index of \( \pi \). Babson and Steingrímsson conjectured that \((\text{des, stat})\) and \((\text{des, maj})\) are equidistributed on \( S_n \). Foata and Zeilberger settled this conjecture using q-enumeration, generating functions and Maple packages ROTA and PERCY. Later, Burstein provided a bijective proof of a refinement of this conjecture. In this paper, we give a new bijective proof of this conjecture.

Keywords: Euler-Mahonian; bijection; involution

1 Introduction

In this paper, we give a new bijective proof of a conjecture of Babson and Steingrímsson [1] on Euler-Mahonian statistics.

Let \( S_n \) denote the set of all the permutations of \([n] = \{1, 2, \ldots, n\}\). Given a permutation \( \pi = \pi_1\pi_2\cdots\pi_n \in S_n \), a descent of \( \pi \) is a position \( i \in [n - 1] \) such that \( \pi_i > \pi_{i+1} \), where \( \pi_i \) and \( \pi_{i+1} \) are called a descent top and a descent bottom, respectively. An ascent of \( \pi \) is a position \( i \in [n - 1] \) such that \( \pi_i < \pi_{i+1} \), where \( \pi_i \) is called an ascent bottom and \( \pi_{i+1} \) is called an ascent top. The descent set and the ascent set of \( \pi \) are given by

\[
\text{Des}(\pi) = \{i : \pi_i > \pi_{i+1}\},
\]

\[
\text{Asc}(\pi) = \{i : \pi_i < \pi_{i+1}\}.
\]
The set of the inversions of $\pi$ is

$$\text{Inv}(\pi) = \{(i, j) : 1 \leq i < j \leq n, \pi_i > \pi_j\}.$$ 

Let $\text{des}(\pi)$, $\text{asc}(\pi)$ and $\text{inv}(\pi)$ be the descent number, the ascent number and the inversion number of $\pi$, which are defined by $\text{des}(\pi) = |\text{Des}(\pi)|$, $\text{asc}(\pi) = |\text{Asc}(\pi)|$ and $\text{inv}(\pi) = |\text{Inv}(\pi)|$, respectively. The major index of $\pi$, denoted $\text{maj}(\pi)$, is given by

$$\text{maj}(\pi) = \sum_{i \in \text{Des}(\pi)} i.$$ 

Suppose that $st_1$ is a statistic on the object $\text{Obj}_1$ and $st_2$ is a statistic on the object $\text{Obj}_2$. If

$$\sum_{\sigma \in \text{Obj}_1} q^{st_1(\sigma)} = \sum_{\sigma \in \text{Obj}_2} q^{st_2(\sigma)},$$

we say that the statistic $st_1$ over $\text{Obj}_1$ is equidistributed with the statistic $st_2$ over $\text{Obj}_2$.

A statistic on $S_n$ is said to be Eulerian if it is equidistributed with the statistic $\text{des}$ on $S_n$. While a statistic on $S_n$ is said to be Mahonian if it is equidistributed with the statistic $\text{inv}$ on $S_n$. It is well-known that

$$\sum_{\pi \in S_n} q^{\text{inv}(\pi)} = \sum_{\pi \in S_n} q^{\text{maj}(\pi)} = [n]_q!,$$

where $[n]_q = 1 + q + \cdots + q^{n-1}$ and $[n]_q! = [n]_q[n - 1]_q \cdots [1]_q$. Thus, the major index $\text{maj}$ is a Mahonian statistic. A pair of statistics on $S_n$ is said to be Euler-Mahonian if it is equidistributed with the joint distribution of the descent number and the major index.

In [1], Babson and Steingrímsson introduced generalized permutation patterns, where they allow the requirement that two adjacent letters in a pattern must be adjacent in the permutation. Let $\mathcal{A}$ be the alphabet $\{a, b, c, \ldots\}$ with the usual ordering. We write patterns as words in $\mathcal{A}$, where two adjacent letters may or may not be separated by a dash. Two adjacent letters without a dash in a pattern indicates that the corresponding letters in the permutation must be adjacent. Given a generalized pattern $\tau$ and a permutation $\pi$, we say a subsequence of $\pi$ is an occurrence (or instance) of $\tau$ in $\pi$ if it is order-isomorphic to $\tau$ and satisfies the above dash conditions. Let $(\tau)\pi$ denote the number of occurrences of $\tau$ in $\pi$. Here, we see $(\tau)$ as a generalized pattern function. For example, an occurrence of the generalized pattern $b-ca$ in a permutation $\pi = \pi_1\pi_2\cdots\pi_n$ is a subsequence $\pi_i\pi_j\pi_{j+1}$ such that $i < j$ and $\pi_{j+1} < \pi_i < \pi_j$. For $\pi = 4753162$, we have $(b-ca)\pi = 4$.

Further, Babson and Steingrímsson [1] showed that almost all of the Mahonian permutation statistics in the literature can be written as linear combinations of generalized patterns. We list some of them below.

$$\text{maj} = (a - cb) + (b - ca) + (c - ba) + (ba),$$

$$\text{stat} = (ac - b) + (ba - c) + (cb - a) + (ba).$$

They conjectured that the statistic $(\text{des, stat})$ is Euler-Mahonian.
Conjecture 1. The distribution of the bistatistic \((\text{des}, \text{stat})\) is equal to that of \((\text{des}, \text{maj})\).

In 2001, D. Foata and D. Zeilberger [4] gave a proof of this conjecture using \(q\)-enumeration and generating functions and an almost completely automated proof via Maple packages ROTA and PERCY.

Given a permutation \(\pi = \pi_1 \pi_2 \ldots \pi_n\), let \(F(\pi) = \pi_1\) be the first letter of \(\pi\) and

\[
\text{adj}(\pi) = |\{i: 1 \leq i \leq n \text{ and } \pi_i - \pi_{i+1} = 1\}|
\]

where \(\pi_{n+1} = 0\). Burstein [2] provided a bijective proof of the following refinement of Conjecture 1 as follows.

Theorem 2. The statistics \((\text{adj}, \text{des}, F, \text{maj}, \text{stat})\) and \((\text{adj}, \text{des}, F, \text{stat}, \text{maj})\) are equidistributed over \(S_n\) for all \(n\).

In this paper, we will give a new bijective proof of Conjecture 1, which does not preserve the statistic \(\text{adj}\).

2 A new bijective proof of Conjecture 1

In this section, we recall a particular bijection \(\varphi\) on \(S_n\) that maps the inversion number to the major index, which is due to Carlitz [3] and stated more clearly in [6] and [7]. Based on this, we give an analogous bijection which proves Conjecture 1.

To give a description of \(\varphi\), we first recall two labeling schemes for permutations. It involves accounting for the effects of inserting a new largest element into a permutation, and so it is known as the insertion method.

Given a permutation \(\sigma = \sigma_1 \sigma_2 \ldots \sigma_{n-1}\) in \(S_{n-1}\). To obtain a permutation \(\pi \in S_n\), we can insert \(n\) in \(n\) spaces, namely, immediately before \(\sigma_1\) or immediately after \(\sigma_i\) for \(1 \leq i \leq n\). In order to keep track of how the insertion of \(n\) affects the inversion number and the major index, we may define two labelings of the \(n\) inserting spaces.

The inv-labeling of \(\sigma\) is given by numbering the spaces from right to left with 0, 1, ..., \(n-1\). The maj-labeling of \(\sigma\) is obtained by labeling the space after \(\sigma_{n-1}\) with 0, labeling the descents from right to left with 1, 2, ..., \(\text{des}(\sigma)\) and labeling the remaining spaces from left to right with \(\text{des}(\sigma) + 1, \ldots, n\). As an example, let \(\sigma = 13287546\), the inv-labeling of \(\sigma\) is

\[
81362573524160,
\]

while the maj-labeling of \(\sigma\) is given by

\[
8163427837514860.
\]

For \(n \geq 2\), we define the map

\[
\phi_{\text{inv},n}: \{0, 1, \ldots, n-1\} \times S_{n-1} \rightarrow S_n
\]
by setting $\phi_{\text{inv},n}(i, \sigma)$ to be the permutation obtained by inserting $n$ in the space labeled $i$ in the inv-labeling of $\sigma$. By changing the inv-labeling to maj-labeling, we obtain the map $\phi_{\text{maj},n}$. As an example,

$$\phi_{\text{inv},9}(3, 13287546) = 132879546$$

and

$$\phi_{\text{maj},9}(3, 13287546) = 132897546.$$

For maps $\phi_{\text{inv},n}$ and $\phi_{\text{maj},n}$, we have the following two lemmas.

**Lemma 3.** For $\sigma \in S_{n-1}$ and $i \in \{0,1,\ldots,n-1\}$, we have

$$\text{inv}(\phi_{\text{inv},n}(i, \sigma)) = \text{inv}(\sigma) + i.$$

**Lemma 4.** For $\sigma \in S_{n-1}$ and $i \in \{0,1,\ldots,n-1\}$, we have

$$\text{maj}(\phi_{\text{maj},n}(i, \sigma)) = \text{maj}(\sigma) + i.$$

Lemma 3 is easy to verified. For a detailed proof of Lemma 4, see [5].

Given a permutation $\pi \in S_n$, let $\pi^{(i)}$ be the restriction of $\pi$ to the letters $1, 2, \ldots, i$ for $1 \leq i \leq n$. For $2 \leq i \leq n$, let

$$(c_i, \pi^{(i-1)}) = \phi_{\text{inv},i}^{-1}(\pi^{(i)}),$$

$$(m_i, \pi^{(i-1)}) = \phi_{\text{maj},i}^{-1}(\pi^{(i)}).$$

By setting $c_1 = 0$ and $m_1 = 0$, we obtain two sequences $c_1c_2\cdots c_n$ and $m_1m_2\cdots m_n$ in $E_n$, where

$$E_n = \{w = w_1\cdots w_n | w_i \in [0, i-1], 1 \leq i \leq n\}.$$ 

Define $\gamma(\pi) = c_1c_2\cdots c_n$ and $\mu(\pi) = m_1m_2\cdots m_n$. It is not hard to check that both $\gamma$ and $\mu$ are bijections. The sequence $c_1c_2\cdots c_n$ is called the inversion table of $\pi$, while $m_1m_2\cdots m_n$ is called the major index table of $\pi$. Moreover, we have $\sum_{i=1}^{\pi} c_i = \text{inv}(\pi)$ and $\sum_{i=1}^{\pi} m_i = \text{maj}(\pi)$. As an example, let $\pi = 13287546$, then $\pi^{(8)} = \pi$ and $\mu(\pi) = 00204056$ as computed in Table 1.

Now, we can define the bijection $\varphi$ that maps the inversion number to the major index by letting $\varphi = \mu^{-1}\gamma$. Clearly, $\varphi$ is a bijection which proves that statistics $\text{inv}$ and $\text{maj}$ are equidistributed over $S_n$.

Table 1: The computation of the major index table of 13287546.
In the following of this section, we will construct a bijection $\rho$ to prove Conjecture 1, which is, to some extent, an analogue of the above bijection $\varphi$.

First, we define a stat-labeling of $\sigma \in S_n$. Label the descents of $\sigma$ and the space after $\sigma_n$ by $0, 1, \ldots, des(\sigma)$ from left to right. Label the space before $\sigma_0$ by $des(\sigma) + 1$. The ascents of $\sigma$ are labeled from right to left by $des(\sigma) + 2, \ldots, n$. As an example, for $\sigma = 13287546$, we have the stat-labeling of $\sigma$ as follows\[ 5_13_63_02_78_17_25_34_66_4. \]

Based on the stat-labeling, we define the map $\phi_{stat,n}$ for $n \geq 2$. For a permutation $\sigma = \sigma_1\sigma_2\ldots\sigma_{n-1}$ and $0 \leq i \leq n - 1$, define $\phi_{stat,n}(i, \sigma)$ to be the permutation obtained by inserting $n$ in the position labeled $i$ in the stat-labeling of $\sigma$. For instance, $\phi_{stat,9}(7, 13287546) = 132987546$.

It should be noted that unlike the properties of $\phi_{inv,n}$ and $\phi_{maj,n}$ stated in Lemma 3 and Lemma 4, we deduce that $\phi_{stat,n}(i, \sigma)) \neq stat(\sigma) + i$ for $i = des(\sigma) + 1$. For the map $\phi_{stat,n}$, we have the following property.

Lemma 5. For $\sigma \in S_{n-1}$ and $i \in \{0, 1, \ldots, des(\sigma), des(\sigma) + 2, \ldots, n - 1\}$, we have
\[ stat(\phi_{stat,n}(i, \sigma)) = stat(\sigma) + i. \]

Proof. First, we recall that $stat = (ac-b) + (ba-c) + (cb-a) + (ba)$. To prove this lemma, we have to consider the changes of the statistic $stat$ brought by inserting $n$ into $\sigma$. Assume that $\sigma = \sigma_1\sigma_2\ldots\sigma_{n-1}$, there are three cases for us to consider.

- **Case 1**: $n$ is inserted into the space after $\sigma_{n-1}$.

  Write $\pi = \sigma n$. Clearly, the insertion of $n$ does not bring new $ac-b$, $cb-a$, and $ba$ patterns. While $n$ can form new $ba-c$ patterns of $\pi$ with the $ba$ patterns of $\sigma$. It follows that $stat(\pi) - stat(\sigma) = (ba)\sigma = des(\sigma)$. Notice that the label of the space after $\sigma_{n-1}$ is $des(\sigma)$. Hence, in this case the lemma holds.

- **Case 2**: $n$ is inserted into a descent.

  Suppose that $\tau$ is the permutation obtained by inserting $n$ to the position $i$ and $\sigma_i > \sigma_{i+1}$. Moreover, let this descent be the $k$-th descent from left to right. We claim that $stat(\tau) - stat(\sigma) = k - 1$.

  The insertion of $n$ forms some new $ac-b$ patterns, and the number of these new patterns is $|\{j, j > i \text{ and } \sigma_j > \sigma_i\}|$. Moreover, $n$ forms $k - 1$ new $ba-c$ patterns with the former $k - 1$ descents, while it destroys the $ba-c$ patterns of $\sigma$ by the number $|\{j, j > i \text{ and } \sigma_j > \sigma_i\}|$. It is easy to verify the functions $(cb-a)$ and $(ba)$ do not change. Hence, we conclude that $stat(\tau) - stat(\sigma) = k - 1$. The claim is verified. Notice that the label of the $k$-th descent from left to right is also $k - 1$. It follows that the lemma holds for this case.

- **Case 3**: $n$ is inserted into an ascent.
Lemma 6. For \( \pi \in S_n \), we have \( F(\pi) = F(\rho(\pi)) \) and \( \text{des}(\pi) = \text{des}(\rho(\pi)) \).

**Proof.** Suppose that \( \sigma = \rho(\pi) \) and \( k = F(\pi) \). We proceed to show that \( F(\sigma^{(i)}) = F(\pi^{(i)}) = k \) and \( \text{des}(\sigma^{(i)}) = \text{des}(\pi^{(i)}) \) for \( k \leq i \leq n \) by induction. Let \( \pi^{(k)} = k p_2 \cdots p_k \),

Table 2: The computation of the stat table of 52718346.
then we have \( \sigma^{(k)} = k(k-p_k)(k-p_{k-1}) \cdots (k-p_2) \). It is routine to check that \( F(\sigma^{(k)}) = F(\pi^{(k)}) = k \) and \( \text{des}(\sigma^{(k)}) = \text{des}(\pi^{(k)}) \), hence, we omit the details here.

Now assume that \( \text{des}(\sigma^{(l)}) = \text{des}(\pi^{(l)}) = d \) and \( F(\sigma^{(l)}) = F(\pi^{(l)}) = k \) for \( k \leq l \leq n-1 \). We proceed to show that \( \text{des}(\sigma^{(l+1)}) = \text{des}(\pi^{(l+1)}) \) and \( F(\sigma^{(l+1)}) = F(\pi^{(l+1)}) = k \).

Let \( s = s_1 s_2 \cdots s_n = \nu(\pi) \). By the constructions of \( \nu \) and \( \rho \), we may see that \( \pi^{(l+1)} = \phi_{\text{stat},l+1}(s_{l+1}, \pi^{(l)}) \) and \( \sigma^{(l+1)} = \phi_{\text{maj},l+1}(s_{l+1}, \sigma^{(l)}) \). Notice that both in the maj-labeling of \( \sigma^{(l)} \) and the stat-labeling of \( \pi^{(l)} \), the descents and the space after the last letter are labeled by \( \{0, 1, \ldots, d\} \), the space before the first element is labeled by \( d+1 \), and the ascents are labeled by \( \{d+2, \ldots, l\} \). Since \( F(\pi^{(l)}) = k = F(\pi) \), it is easy to see that \( s_{l+1} \neq d+1 \). It follows that \( F(\sigma^{(l+1)}) = F(\pi^{(l+1)}) = k \).

If \( s_{l+1} < d+1 \), then \( l+1 \) is inserted into the descents or the space after the last element of \( \pi^{(l)} \) and \( \sigma^{(l)} \). Hence, we deduce that \( \text{des}(\sigma^{(l+1)}) = \text{des}(\pi^{(l+1)}) = d \). If \( s_{l+1} > d+1 \), then \( l+1 \) is inserted into the ascents of \( \pi^{(l)} \) and \( \sigma^{(l)} \). Hence, we deduce that \( \text{des}(\sigma^{(l+1)}) = \text{des}(\pi^{(l+1)}) = d + 1 \). Combining the two cases above, we have \( \text{des}(\sigma^{(l+1)}) = \text{des}(\pi^{(l+1)}) \).

Notice that \( \sigma^{(n)} = \sigma \) and \( \pi^{(n)} = \pi \), we complete the proof. \( \square \)

Base on the construction of \( \rho \) and Lemma 6, we have the following theorem.

**Theorem 7.** The map \( \rho \) is an involution on \( S_n \).

**Proof.** Given a permutation \( \pi \in S_n \), it suffices for us to show that \( \rho^2(\pi) = \pi \). That is, writing \( \sigma = \rho(\pi) \), we need to show that \( \rho(\sigma) = \pi \).

Let \( F(\pi) = k \), then by Lemma 6, we know that \( k = F(\pi) = F(\sigma) \). Write \( \pi^{(k)} = kp_2 \cdots p_k \), then we have \( \sigma^{(k)} = k(k-p_k) \cdots (k-p_2) \). Assume that \( \nu(\pi) = s = s_1 s_2 \cdots s_n \) and \( \mu(\sigma) = m_1 m_2 \cdots m_n \). By the construction of \( \rho \), we have \( \sigma^{(i)} = \phi_{\text{maj},i}(s_i, \sigma^{(i-1)}) \) for \( k+1 \leq i \leq n \). It follows that \( m_i = s_i \) for \( k+1 \leq i \leq n \).

Suppose that \( \alpha = \rho(\sigma) \), in the following, we proceed to show that \( \alpha^{(i)} = \pi^{(i)} \) for \( k \leq i \leq n \) by induction. By the definition of \( \rho \), we have \( \alpha^{(k)} = kp_2 \cdots p_k = \pi^{(k)} \). Assume that \( \alpha^{(i)} = \pi^{(i)} \) holds for \( k \leq i \leq n-1 \), we aim to show that \( \alpha^{(i+1)} = \pi^{(i+1)} \). To achieve this, we need to mention the following property of the maj-labeling and the stat-labeling of a single permutation.

For a permutation \( p \in S_n \), assume the maj-labeling of \( p \) is \( f_0 f_1 \cdots f_n \), while the stat-

Table 3: The computation of \( \rho(52718346) \).

Proposition 8. For any labeling of \( p \) is \( h_0 h_1 \cdots h_n \). Then it is easily checked that

\[
f_i + h_i = \begin{cases} 
\text{des}(p), & \text{if } i \text{ is a descent of } p \text{ or } i = n, \\
n + \text{des}(p) + 2, & \text{if } i \text{ is an ascent of } p, \\
2\text{des}(p) + 2, & \text{if } i = 0. 
\end{cases}
\]  
(1)

Let \( \nu(\sigma) = l_1 l_2 \cdots l_n \) and \( d = \text{des}(\alpha(i)) \). Then, we have

\[
\alpha(i+1) = \phi_{\text{maj},i+1}(l_{i+1}, \alpha(i)) = \begin{cases} 
\phi_{\text{stat},i+1}(d - l_{i+1}, \alpha(i)), & \text{if } 0 \leq l_{i+1} \leq d, \\
\phi_{\text{stat},i+1}(n + d + 2 - l_{i+1}, \alpha(i)), & \text{if } d + 2 \leq l_{i+1} \leq n. 
\end{cases}
\]

By the proof of Lemma 6, we see that \( \text{des}(\sigma(i)) = \text{des}(\alpha(i)) = d \). Recall that \( \nu(\sigma) = l_1 l_2 \cdots l_n \) and \( \mu(\sigma) = m_1 m_2 \cdots m_n \). Hence, it follows from (1) that

\[
\alpha(i+1) = \phi_{\text{stat},i+1}(m_{i+1}, \alpha(i)) = \phi_{\text{stat},i+1}(s_{i+1}, \pi(i)) = \pi^{(i+1)}.
\]

Notice that \( \alpha = \alpha^{(n)} \) and \( \pi = \pi^{(n)} \). Hence, we have \( \pi = \nu(\sigma) \), namely, \( \nu^2(\pi) = \pi \). This completes the proof. \( \square \)

Indeed, the involution \( \nu \) also preserves some additional statistics, which is stated in the following proposition.

**Proposition 8.** For any \( \pi = \pi_1 \pi_2 \cdots \pi_n \in S_n \), we have \( \text{maj}(\nu(\pi)) = \text{stat}(\pi) \) and \( \text{stat}(\nu(\pi)) = \text{maj}(\pi) \).

**Proof.** Write \( \sigma = \nu(\pi) \). Let \( k = F(\pi) \) and \( \pi^{(k)} = kp_2 \cdots p_k \). Then we have \( \sigma^{(k)} = k(p_k - p_{k-1}) \cdots (p_k - p_2) \). In the following, we will show that \( \text{maj}(\sigma^{(i)}) = \text{stat}(\pi^{(i)}) \) for \( k \leq i \leq n \) by induction.

First, we show that \( \text{maj}(\sigma^{(k)}) = \text{stat}(\pi^{(k)}) \). By the proof of Lemma 6, we have \( \text{des}(\sigma^{(k)}) = \text{des}(\pi^{(k)}) \). Hence \( (ba)\pi^{(k)} = (ba)\sigma^{(k)} \). It suffices for us to show that

\[
(ac - b)c^{(k)} + (ba - c)c^{(k)} + (cb - a)c^{(k)} = (ac - b)c^{(k)} + (cb - a)c^{(k)} + (cb - a)c^{(k)} \tag{2}
\]

Given a pattern \( p = p_1 p_2 \cdots p_k \), by putting a line under \( p_1 \) (resp. \( p_k \)), we mean that an instance of \( p \) must begin (resp. end) with the leftmost (resp. rightmost) letter of the permutation. By putting a dot under \( p_1 \), we mean that an instance of \( p \) must not begin with the leftmost letter. For instance, \( (cb-a) \) is a function which maps a permutation, say \( \tau = \tau_1 \tau_2 \cdots \tau_n \), to \( |\{i, \tau_1 \tau_2 \tau_i \text{ forms a 321 pattern of } \tau \}| \).

By the definition of \( \nu \), we know that

\[
(ac - b)c^{(k)} + (ba - c)c^{(k)} + (cb - a)c^{(k)}
=(ac - b)c^{(k)} + (ba - c)c^{(k)} + (cb - a)c^{(k)} + (cb - a)c^{(k)}
\]
Hence, to prove (2), we need to prove that for any permutation \( p \) of \( S_k \) with \( p_1 = k \),

\[(c - ba)p + (b - ca)p = (c - ba)p + (b - ac)p. \quad (3)\]

We define sets \( A(p), C(p) \) and multisets \( B(p), D(p) \) as follows.

\[
\begin{align*}
A(p) &= \{ p_i : p_i p_{i+1} \text{ forms a 321 pattern of } p \}, \\
B(p) &= \{ p_i : p_i p_{j+1} \text{ forms a 231 pattern of } p \}, \\
C(p) &= \{ p_i : p_i p_{j+1} \text{ forms a 321 pattern of } p \}, \\
D(p) &= \{ p_i : p_i p_{j+1} \text{ forms a 213 pattern of } p \}.
\end{align*}
\]

To prove (3), it is enough to show that \( A \cup B = C \cup D \), where the union operator is a multiset union. First, we show that \( C \cup D \subseteq A \cup B \).

Let \( p_k = a \), then we know that \( C(p) = \{ a + 1, a + 2, \ldots, k - 1 \} \). If \( p_i \in C(p) \) is a descent top, it is easy to see that \( p_i \in A(p) \). If \( p_i \in C(p) \) is an ascent bottom, we claim that \( p_i \in B(p) \). This claim will be proved together with case 4 in the following.

Given an element \( p_i \) in \( D(p) \), if the multiplicity of \( p_i \) is \( x \), there exists a set

\[\{ j_1, j_1 + 1, j_2, j_2 + 1, \ldots, j_x, j_x + 1 \},\]

which is ordered by increasing order, satisfying that

\[p_ip_jp_{j+1}, p_ip_jp_{j+1}, \ldots, p_ip_jp_{j+1}\]

are instances of 213 pattern. We claim that there exists \( j_1 + 1 \leq r_1 < j_2 \) such that \( p_ip_{r_1}p_{r_1+1} \) forms a 231 pattern.

Choose the smallest \( g_1 \) such that \( j_1 + 1 \leq g_1 < j_2 \) and \( g_1 \) is a descent. If \( p_{g_1+1} < p_i \), then \( p_ip_{g_1}p_{g_1+1} \) forms a 231 pattern, the claim is verified. Otherwise, we seek the smallest \( g_1 + 1 \leq g_2 < j_2 \) such that \( g_2 \) is a descent. If \( p_{g_2+1} < p_i \), the claim is verified. If not, we repeat the above process. Since \( p_i > p_{j_2} \), the process must be terminated. Hence, the claim is verified. By a similar means, we deduce that there exists \( j_1 + 1 \leq r_1 < j_{i+1} \) where \( 1 \leq l < x - 1 \) such that \( p_ip_{r_1}p_{r_1+1} \) forms a 231 pattern. The claim is verified.

To analyze the element \( p_i \) in \( D(p) \), we consider four cases.

- \( p_i \) is a descent top and \( 1 < p_i \leq a - 1 \).

Suppose that the multiplicity of \( p_i \) of this type in \( D(p) \) is \( x \). By the above statement, we see that \( p_ip_{r_1}p_{r_1+1} \) forms a 231 pattern, where \( j_1 + 1 \leq r_1 < j_{i+1} \) and \( 1 \leq l \leq x - 1 \). Thus, we deduce that there are \( x - 1 \) \( p_i \)'s in \( B(p) \). Notice that there is one \( p_i \) left in \( B(p) \). Clearly, we can set this \( p_i \) to be the element of \( A(p) \) consisting of \( p_1, p_i \) and \( p_{i+1} \).

- \( p_i \) is an ascent bottom and \( 1 \leq p_i \leq a - 1 \).
Suppose that the multiplicity of \( p_i \) of this type in \( D(p) \) is \( x \). Similarly, we know that \( p_ip_{r_1}p_{r_1+1} \) forms a 231 pattern, where \( j_1 + 1 \leq r_1 < j_{i+1} \) and \( 1 \leq l \leq x - 1 \). Since \( p_i < p_{i+1} \), we have \( j_1 > i + 1 \). Based on this, it can be easily seen that there exists \( r_0 \) such that \( i + 1 \leq r_0 < j_1 \) and \( p_ip_{r_0}p_{r_0+1} \) forms a 231 pattern. Hence, we deduce that in this case there are \( x \) \( p_i \)'s in \( B(p) \).

- \( p_i \) is a descent top and \( a + 1 \leq p_i \leq k - 1 \).

Suppose that the multiplicity of \( p_i \) of this type in \( D(p) \) is \( x \). Similarly, we deduce that \( p_ip_{r_1}p_{r_1+1} \) forms a 231 pattern, where \( j_1 + 1 \leq r_1 < j_{i+1} \) and \( 1 \leq l \leq x - 1 \). What’s more, it follows from \( p_i > a \) that there exists \( j_x \leq r_x < m \) such that \( p_ip_{r_i}a \) forms a 231 pattern. Hence, we deduce that \( p_i \) in \( B(p) \) and its multiplicity is \( x \). Similarly with the above cases, we deduce that \( p_ip_{r_1}p_{r_1+1} \) forms a 231 pattern, where \( j_1 + 1 \leq r_1 < j_{i+1} \) and \( 1 \leq l \leq x - 1 \). Since \( p_i > a \), there exists \( j_x \leq r_x < m \) such that \( p_ip_{r_i}a \) forms a 231 pattern. By \( p_i < p_{i+1} \), we have \( j_1 > i + 1 \). Based on this, it can be easy seen that there exists \( r_0 \) such that \( i + 1 \leq r_0 < j_1 \) and \( p_ip_{r_0}p_{r_0+1} \) forms a 231 pattern. Hence, we deduce that \( p_i \) in \( B(p) \) and its multiplicity is \( x + 1 \).

Combining all above, we deduce that \( C \cup D \subseteq A \cup B \). By a similar analysis, we can prove that \( A \cup B \subseteq C \cup D \). We omit it here. As an example, if \( p = 978452613 \), we have \( A(p) = \{5, 6, 8\} \), \( B(p) = \{2, 4, 4, 5, 7\} \), \( C(p) = \{4, 5, 6, 7, 8\} \) and \( D(p) = \{2, 4, 5\} \). It can be verified that \( A \cup B = C \cup D \). This proves that \( \text{maj}(\sigma^{(k)}) = \text{stat}(\pi^{(k)}) \).

Now assume that \( \text{maj}(\sigma^{(i)}) = \text{stat}(\pi^{(i)}) \) for \( k \leq i \leq n - 1 \), we proceed to show that \( \text{maj}(\sigma^{(i+1)}) = \text{stat}(\pi^{(i+1)}) \). Write \( \nu(\pi) = s_1s_2 \cdots s_n \). Then, by Lemma 4, Lemma 5 and the construction of \( \rho \), we have

\[
\text{maj}(\sigma^{(i+1)}) = s_{i+1} + \text{maj}(\sigma^{(i)})
\]

\[
= s_{i+1} + \text{stat}(\pi^{(i)})
\]

\[
= \text{stat}(\pi^{(i+1)}).
\]

This proves \( \text{maj}(\sigma^{(i)}) = \text{stat}(\pi^{(i)}) \) for \( k \leq i \leq n \). Notice that \( \pi = \pi^{(n)} \) and \( \sigma = \sigma^{(n)} \). We deduce that \( \text{maj}(\sigma) = \text{maj}(\rho(\pi)) = \text{stat}(\pi) \). By Theorem 7, we see that \( \rho \) is an involution. This implies that \( \text{stat}(\rho(\pi)) = \text{maj}(\pi) \). This completes the proof.

Combining Lemma 6, Theorem 7 and Proposition 8, we give a proof of Conjecture 1.

It should be mentioned that Burstein [2] provided a direct bijective proof of a refinement of Conjecture 1. The bijection \( \chi \) is given as follows. Given a permutation \( \pi \in S_n \) with \( F(\pi) = k \). Let \( \pi' = \chi(\pi) \) with \( \pi'(1) = k \) and

\[
\pi'(i) = \begin{cases} 
    k - \pi(n + 2 - i), & \text{if } \pi(n + 2 - i) < k, \\
    n + k + 1 - \pi(n + 2 - i), & \text{if } \pi(n + 2 - i) > k.
\end{cases}
\] (4)
In addition to preserving the statistics $\text{des}$ and $F$, the bijection $\chi$ also preserves the statistic $\text{adj}$, while our bijection does not. As an example, set $\pi = 543617982$, then $\rho(\pi) = \sigma = 539784621$ and $\chi(\pi) = \pi' = 537684921$. It can be checked that $\text{adj}(\pi) = \text{adj}(\pi')$, while $\text{adj}(\pi) \neq \text{adj}(\sigma)$. Moreover, it is easily seen that for $\pi \in S_n$ with $F(\pi) = n$, we have $\rho(\pi) = \chi(\pi) = \sigma$. We note that in this case both Burstein and us have to prove $\text{maj}(\sigma) = \text{stat}(\pi)$. Different from our proof in Proposition 8, Burstein gave the following two relations, which implies that $\text{maj}(\sigma) = \text{stat}(\pi)$.

\[
\text{maj}(\pi) + \text{stat}(\pi) = (n + 1)\text{des}(\pi) - (F(\pi) - 1), \\
\text{maj}(\pi) + \text{maj}(\sigma) = (n + 1)\text{des}(\pi) - (F(\pi) - 1).
\]
