Abstract

Two Steiner triple systems $(X, \mathcal{A})$ and $(X, \mathcal{B})$ are said to intersect in m pairwise disjoint blocks if $|\mathcal{A} \cap \mathcal{B}| = m$ and all blocks in $\mathcal{A} \cap \mathcal{B}$ are pairwise disjoint. For each v , we completely determine the possible values of m such that there exist two Steiner triple systems of order v intersecting in m pairwise disjoint blocks.

1 Introduction

A *set system* is a pair $(X, \mathcal{A})$, where X is a finite set of *points*, and $\mathcal{A}$ is a set of subsets of X , called *blocks*. Let $\mathcal{K}$ be a set of positive integers. The set $\mathcal{K}$ is a *set of block sizes* for $(X, \mathcal{A})$ if $|A| \in \mathcal{K}$ for every $A \in \mathcal{A}$.

Let $(X, \mathcal{A})$ be a set system, and let $\mathcal{G} = \{G_1, \dots, G_s\}$ be a partition of X into subsets, called *groups*. The triple $(X, \mathcal{G}, \mathcal{A})$ is a *group divisible design* (GDD) when every 2-subset of X not contained in a group appears in exactly one block and $|A \cap G| \leq 1$ for all $A \in \mathcal{A}$ and $G \in \mathcal{G}$. We denote a GDD $(X, \mathcal{G}, \mathcal{A})$ by $\mathcal{K}$ -GDD if $\mathcal{K}$ is a set of block sizes for $(X, \mathcal{A})$. The *group type*, or simply *type* of a GDD $(X, \mathcal{G}, \mathcal{A})$ is the multiset $[|G| \mid G \in \mathcal{G}]$. When more convenient, we use the exponential notation to describe the type of a GDD: A GDD of type $g_1^{t_1} \cdots g_s^{t_s}$ is a GDD where there are exactly t_i groups of size g_i . If $\mathcal{G}$ is not specified in a GDD $(X, \mathcal{G}, \mathcal{A})$, it is taken that all groups are of size one: $\mathcal{G} = \{\{x\} \mid x \in X\}$. A $\{3\}$ -GDD of type 1^v is a *Steiner triple system* of order v , and is denoted by $\text{STS}(v)$.

Two GDDs $\mathcal{D}_1 = (X, \mathcal{G}_1, \mathcal{A}_1)$ and $\mathcal{D}_2 = (X, \mathcal{G}_2, \mathcal{A}_2)$ of the same type are said to *intersect in m blocks* if $|\mathcal{A}_1 \cap \mathcal{A}_2| = m$. If in addition, the blocks in $\mathcal{A}_1 \cap \mathcal{A}_2$ are pairwise disjoint (that is, for any $A, A' \in \mathcal{A}_1 \cap \mathcal{A}_2$, $A \neq A'$, we have $A \cap A' = \emptyset$), then $\mathcal{D}_1$ and $\mathcal{D}_2$

are said to *intersect in m pairwise disjoint blocks*. Define

$$\begin{aligned}\text{Int}(T) &= \{m \mid \exists \text{ two } \{3\}\text{-GDDs of type } T \text{ intersecting in } m \text{ blocks}\}; \text{ and} \\ \text{Int}_d(T) &= \{m \mid \exists \text{ two } \{3\}\text{-GDDs of type } T \text{ intersecting in } m \text{ pairwise disjoint blocks}\}.\end{aligned}$$

The *intersection problem* and *disjoint intersection problem* for $\{3\}$ -GDDs of type T is to determine $\text{Int}(T)$ and $\text{Int}_d(T)$, respectively. A pair of GDDs is said to be *disjoint* if they intersect in no blocks.

The intersection problem for Steiner triple systems was completely solved by Lindner and Rosa [6]. The intersection problem for $\{3\}$ -GDDs of type 2^t has also been solved by Hoffman and Lindner [5]. The case of $\{3\}$ -GDDs of type g^3 , which are equivalent to Latin squares of side g , has been settled by Fu [4]. Butler and Hoffman [2] finally put the intersection problem for $\{3\}$ -GDDs of type g^t to rest with the following result.

Let $b(g^t) = g^2 t(t-1)/6$ (the number of blocks in a $\{3\}$ -GDD of type g^t), and denote by $\mathcal{I}(g^t) = \{0, 1, \dots, b(g^t)\} \setminus \{b(g^t) - 5, b(g^t) - 3, b(g^t) - 2, b(g^t) - 1\}$.

Theorem 1.1 (Butler and Hoffman) *Let g and t be positive integers such that $t \geq 3$, $g^2 \binom{t}{2} \equiv 0 \pmod{3}$, and $g(t-1) \equiv 0 \pmod{2}$. Then $\text{Int}(g^t) = \mathcal{I}(g^t)$, except that*

- (i) $\text{Int}(1^9) = \mathcal{I}(1^9) \setminus \{5, 8\}$;
- (ii) $\text{Int}(2^4) = \mathcal{I}(2^4) \setminus \{1, 4\}$;
- (iii) $\text{Int}(3^3) = \mathcal{I}(3^3) \setminus \{1, 2, 5\}$; and
- (iv) $\text{Int}(4^3) = \mathcal{I}(4^3) \setminus \{5, 7, 10\}$.

While the intersection problem has received considerable attention, the disjoint intersection problem seems not to be well-studied. The purpose of this paper is to determine completely $\text{Int}_d(1^v)$. This is the disjoint intersection problem for $\text{STS}(v)$. Hence, we assume throughout this paper that $v \equiv 1, 3 \pmod{6}$. Note that since $0, 1 \in \text{Int}(1^v)$, we also have $0, 1 \in \text{Int}_d(1^v)$.

Define

$$\mathcal{I}_d(1^v) = \begin{cases} \{0, 1, \dots, (v-1)/3\} & \text{if } v \equiv 1 \pmod{6}, \\ \{0, 1, \dots, v/3\} & \text{if } v \equiv 3 \pmod{6}. \end{cases}$$

Since there can be at most $\lceil v/3 \rceil$ pairwise disjoint blocks in an $\text{STS}(v)$, we have $\text{Int}_d(1^v) \subseteq \mathcal{I}_d(1^v)$. So in the remaining of this paper, we shall focus on showing membership of elements of $\mathcal{I}_d(1^v)$ in $\text{Int}_d(1^v)$, rather than the other way round.

2 Latin Squares Intersecting in a Transversal

A *Latin square* of side n is an $n \times n$ array with the property that every row and every column contains every element from $\{1, \dots, n\}$ exactly once. A Latin square A of side n is *idempotent* if $A(i, i) = s_i$ for $1 \leq i \leq n$. A *transversal* in a Latin square of side n is a

set of n cells, no two from the same row or from the same column, or contain the same entry. The *intersection* of two Latin squares A and B is the set of cells (i, j) such that $A(i, j) = B(i, j)$. In this section, we show that for $n \neq 2, 3, 6$, there exists a pair of Latin squares of side n intersecting in a transversal.

Two Latin squares A and B of side n are said to be *orthogonal* if the n^2 ordered pairs $(A(i, j), B(i, j))$ for $1 \leq i, j \leq n$ are all distinct. The following result is well-known (see, for example, [1]).

Theorem 2.1 *There exists a pair of orthogonal idempotent Latin squares of side n for all $n \neq 2, 3, 6$.*

Theorem 2.2 *Let $n \neq 2, 3, 6$. Then there exists a pair of Latin squares of side n intersecting in a transversal.*

Proof. Let A and B be a pair of orthogonal idempotent Latin squares of side n . We claim that A and B intersect in a transversal. Obviously, the transversal formed by the main diagonal of either A or B is in the intersection. It remains to show that for $1 \leq i, j \leq n$, $i \neq j$, we have $A(i, j) \neq B(i, j)$. Suppose on the contrary that $A(i, j) = B(i, j)$. Then we have $(A(i, j), B(i, j)) = (k, k) = (A(k, k), B(k, k))$ for some k . This contradicts the fact that A and B are orthogonal. $\square$

A $\{3\}$ -GDD of type g^3 can be obtained from a Latin square A of side g as follows. Let $R = \{r_1, \dots, r_g\}$ and $C = \{c_1, \dots, c_g\}$ be the set of row and column indices of A , respectively. Let $S = \{1, \dots, n\}$ be the set of entries of A . Define

$$\begin{aligned} X &= R \cup C \cup S; \\ \mathcal{G} &= \{R, C, S\}; \\ \mathcal{A} &= \{\{r_i, c_j, A(i, j)\} \mid 1 \leq i, j \leq g\}. \end{aligned}$$

Then $(X, \mathcal{G}, \mathcal{A})$ is a $\{3\}$ -GDD of type g^3 . From this construction, it is easy to see that Theorem 2.2 implies the following.

Corollary 2.1 *For $g \neq 2, 3, 6$, we have $g \in \text{Int}_d(g^3)$.*

3 Wilson-Type Constructions

Wilson [7] established the following fundamental construction for GDDs which has significant impact on design theory.

Wilson's Fundamental Construction	
Input:	(master) GDD $\mathcal{D} = (X, \mathcal{G}, \mathcal{A})$; weight function $\omega : X \rightarrow \mathbf{Z}_{\geq 0}$; (ingredient) $\mathcal{K}$ -GDD $\mathcal{D}_A = (X_A, \mathcal{G}_A, \mathcal{B}_A)$ of type $[\omega(a) \mid a \in A]$, for each block $A \in \mathcal{A}$, where $X_A = \cup_{a \in A} \{\{a\} \times \{1, \dots, \omega(a)\}\}$ and $\mathcal{G}_A = \{\{a\} \times \{1, \dots, \omega(a)\} \mid a \in A\}$.
Output:	$\mathcal{K}$ -GDD $\mathcal{D}^* = (X^*, \mathcal{G}^*, \mathcal{A}^*)$ of type $[\sum_{x \in G} \omega(x) \mid G \in \mathcal{G}]$, where $X^* = \cup_{x \in X} (\{x\} \times \{1, \dots, \omega(x)\})$, $\mathcal{G}^* = \{\cup_{x \in G} (\{x\} \times \{1, \dots, \omega(x)\}) \mid G \in \mathcal{G}\}$, and $\mathcal{A}^* = \cup_{A \in \mathcal{A}} \mathcal{B}_A$.
Notation:	$\mathcal{D}^* = \text{WFC}(\mathcal{D}, \omega, \{\mathcal{D}_A \mid A \in \mathcal{A}\})$.

We use Wilson's fundamental construction to produce pairs of disjoint GDDs.

Theorem 3.1 *Let $\mathcal{D} = (X, \mathcal{G}, \mathcal{A})$ be a GDD. Let $\omega : X \rightarrow \mathbf{Z}_{\geq 0}$ be a weight function. Suppose that for each block $A \in \mathcal{A}$, there exist a pair of disjoint $\{k\}$ -GDDs of type $[\omega(a) \mid a \in A]$. Then there exists a pair of disjoint $\{k\}$ -GDDs of type $[\sum_{x \in G} \omega(x) \mid G \in \mathcal{G}]$.*

Proof. For each block $A \in \mathcal{A}$, let $\mathcal{D}_A^1 = (X_A, \mathcal{G}_A, \mathcal{B}_A^1)$ and $\mathcal{D}_A^2 = (X_A, \mathcal{G}_A, \mathcal{B}_A^2)$ be a pair of disjoint $\{k\}$ -GDDs of type $[\omega(a) \mid a \in A]$. Let $\mathcal{D}_i^* = \text{WFC}(\mathcal{D}, \omega, \{\mathcal{D}_A^i \mid A \in \mathcal{A}\})$, $i = 1, 2$. Then $\mathcal{D}_1$ and $\mathcal{D}_2$ are $\{k\}$ -GDDs of type $[\sum_{x \in G} \omega(x) \mid G \in \mathcal{G}]$.

We claim that $\mathcal{D}_i^* = (X^*, \mathcal{G}^*, \mathcal{A}_i^*)$, $i = 1, 2$, is a pair of disjoint GDDs. To prove this, we have to establish the following:

$$\mathcal{B}_A^1 \cap \mathcal{B}_A^2 = \emptyset, \text{ for all } A \in \mathcal{A}; \text{ and} \quad (1)$$

$$\mathcal{B}_A^1 \cap \mathcal{B}_B^2 = \emptyset, \text{ for all } A, B \in \mathcal{A}, A \neq B. \quad (2)$$

(1) follows trivially from the fact that $(X_A, \mathcal{G}_A, \mathcal{B}_A^1)$ and $(X_A, \mathcal{G}_A, \mathcal{B}_A^2)$ are disjoint, for all $A \in \mathcal{A}$. To see that (2) holds, note that for $A = \{a_1, \dots, a_k\}$ and $B = \{b_1, \dots, b_k\}$, blocks in $\mathcal{B}_A^1$ have the form $\{y_1, \dots, y_k\}$, where $y_i = (a_i, w)$ for some $w \in \{1, \dots, \omega(a_i)\}$, and blocks in $\mathcal{B}_B^2$ have the form $\{z_1, \dots, z_k\}$, where $z_i = (b_i, w)$ for some $w \in \{1, \dots, \omega(b_i)\}$. Hence $y_i = z_j$ is possible only if $a_i = b_j$. It follows that $\{y_1, \dots, y_k\} = \{z_1, \dots, z_k\}$ only if $A = B$, establishing (2). $\square$

Theorem 3.2 (Colbourn, Hoffman, and Rees) *Let g , t , and u be positive integers. There exists a $\{3\}$ -GDD of type $g^t u^1$ if and only if the following conditions are all satisfied:*

- (i) $t \geq 3$, or $t = 2$ and $u = g$;
- (ii) $u \leq g(t - 1)$;
- (iii) $g(t - 1) + u \equiv 0 \pmod{2}$;
- (iv) $gt \equiv 0 \pmod{2}$;

$$(v) \quad g^2 \binom{t}{2} + gtu \equiv 0 \pmod{3}.$$

Theorem 3.1 together with the existence of some $\{3\}$ -GDDs provided by the above result of Colbourn, Hoffman and Rees [3] yields the following.

Corollary 3.1 *For each type listed in the table below, there exist a pair of disjoint $\{3\}$ -GDDs.*

Type	Type of Master $\{3\}$ -GDD	Weight Function
$3^4 9^1$	$1^4 3^1$	$\omega(\cdot) = 3$
$3^6 15^1$	$1^6 5^1$	$\omega(\cdot) = 3$
$9^t 15^1$, $t \equiv 0 \pmod{2}$, $t \geq 4$	$3^t 5^1$	$\omega(\cdot) = 3$
$9^t 21^1$, $t \equiv 0 \pmod{2}$, $t \geq 4$	$3^t 7^1$	$\omega(\cdot) = 3$
$9^t 27^1$, $t \equiv 0 \pmod{2}$, $t \geq 4$	$3^t 9^1$	$\omega(\cdot) = 3$
$(6s)^t (6r)^1$, $t \geq 3$, $r \leq s(t-1)$, $s^2 \binom{t}{2} + str \equiv 0 \pmod{3}$	$(2s)^t (2r)^1$	$\omega(\cdot) = 3$

Proof. For each desired pair of disjoint $\{3\}$ -GDDs, apply Theorem 3.1 with the listed master GDD, weight function, and use as ingredient GDDs a pair of disjoint $\{3\}$ -GDDs of type 3^3 , which exists by Theorem 1.1. The master GDDs all exist by Theorem 3.2. $\square$

Theorem 3.3 (Filling in Groups) *Suppose there exists a pair of disjoint $\mathcal{K}$ -GDDs of type $[g_1, \dots, g_s]$. Furthermore, for each g_i , $1 \leq i \leq s$, there exists a pair of $\mathcal{L}$ -GDDs of type 1^{g_i} intersecting in m_i pairwise disjoint blocks. Then there exists a pair of $(\mathcal{K} \cup \mathcal{L})$ -GDDs of type $1^{\sum_{i=1}^s g_i}$ intersecting in $\sum_{i=1}^s m_i$ pairwise disjoint blocks.*

Proof. Let $(X, \mathcal{G}, \mathcal{A})$ and $(X, \mathcal{G}, \mathcal{B})$ be a pair of disjoint $\mathcal{K}$ -GDDs of type $[g_1, \dots, g_s]$, where $\mathcal{G} = \{G_1, \dots, G_s\}$ and $|G_i| = g_i$, $1 \leq i \leq s$. For each g_i , $1 \leq i \leq s$, let $(G_i, \mathcal{A}_i)$ and $(G_i, \mathcal{B}_i)$ be a pair of $\mathcal{L}$ -GDDs intersecting in m_i pairwise disjoint blocks. Define

$$\begin{aligned} \mathcal{D}_1 &= (X, \mathcal{A} \cup (\cup_{i=1}^s \mathcal{A}_i)); \text{ and} \\ \mathcal{D}_2 &= (X, \mathcal{B} \cup (\cup_{i=1}^s \mathcal{B}_i)). \end{aligned}$$

$\mathcal{D}_1$ and $\mathcal{D}_2$ are clearly $(\mathcal{K} \cup \mathcal{L})$ -GDDs of type $1^{\sum_{i=1}^s g_i}$. We claim that $\mathcal{D}_1$ and $\mathcal{D}_2$ intersect in $\sum_{i=1}^s m_i$ pairwise disjoint blocks. To see this, note that

- (i) $\mathcal{A} \cap \mathcal{B} = \emptyset$, since $(X, \mathcal{G}, \mathcal{A})$ and $(X, \mathcal{G}, \mathcal{B})$ are disjoint GDDs;
- (ii) for $1 \leq i \leq s$, we have $\mathcal{A} \cap \mathcal{B}_i = \emptyset$ and $\mathcal{B} \cap \mathcal{A}_i = \emptyset$, since any block in $\mathcal{A}$ contains at most one element from each group; and
- (iii) for $1 \leq i, j \leq s$, $i \neq j$, we have $\mathcal{A}_i \cap \mathcal{B}_j = \emptyset$, since groups are pairwise disjoint.

Hence, the blocks that $\mathcal{D}_1$ and $\mathcal{D}_2$ have in common are precisely the blocks in $\cup_{i=1}^s (\mathcal{A}_i \cap \mathcal{B}_i)$. It follows that $\mathcal{D}_1$ and $\mathcal{D}_2$ are the desired pair of GDDs intersecting in $\sum_{i=1}^s m_i$ pairwise disjoint blocks. $\square$

For $A, B \subseteq \mathbf{Z}$, we use the notation $A + B$ to denote the set $\{a + b \mid a \in A \text{ and } b \in B\}$. For $A_i \subseteq \mathbf{Z}$, $1 \leq i \leq n$, we use the notation $\sum_{i=1}^n A_i$ to denote the set $\{a_1 + \cdots + a_n \mid a_i \in A_i, \text{ for } 1 \leq i \leq n\}$.

Corollary 3.2 *If there exists a pair of disjoint $\{3\}$ -GDDs of type $g_1^{t_1} \cdots g_s^{t_s}$, then*

$$\text{Int}_d(1^{\sum_{i=1}^s g_i t_i}) \supseteq \sum_{i=1}^s \sum_{j=1}^{t_i} \text{Int}_d(1^{g_i}).$$

Proof. Apply Theorem 3.3 with GDDs intersecting in the appropriate number of pairwise disjoint blocks. $\square$

The above results are sufficient to settle the case $v \equiv 3 \pmod{6}$.

4 Product Constructions

We use the following Singular Direct Product construction.

Singular Direct Product Construction	
Input:	positive integers u, w, t ; for $i = 1, \dots, t$, (master) $\mathcal{K}$ -GDDs $\mathcal{D}_i = (X_i \cup U, \mathcal{G}_i, \mathcal{A}_i)$ of type $u^1 1^{w_i}$, where U is the group of size u in each GDD; (ingredient) $\mathcal{K}$ -GDD $\mathcal{E} = (\cup_{i=1}^t X_i, \{X_i \mid 1 \leq i \leq t\}, \mathcal{B})$ of type $[w_i \mid 1 \leq i \leq t]$; (fill-in) $\mathcal{K}$ -GDD $\mathcal{F} = (G, \mathcal{C})$ of type 1^u .
Output:	$\mathcal{K}$ -GDD $\mathcal{D}^* = (X^*, \mathcal{A}^*)$ of type $1^{u + \sum_{i=1}^t w_i}$, where $X^* = U \cup (\cup_{i=1}^t X_i)$, and $\mathcal{A}^* = (\cup_{i=1}^t \mathcal{A}_i) \cup \mathcal{B} \cup \mathcal{C}$.
Notation:	$\mathcal{D}^* = \text{SDP}(\{\mathcal{D}_i \mid 1 \leq i \leq t\}, \mathcal{E}, \mathcal{F})$.

Lemma 4.1 *Let $v \equiv 3 \pmod{6}$ and $k \equiv 0, 1 \pmod{3}$, $k \geq 3$. Then*

$$\text{Int}_d(1^{k(v-1)+1}) \supseteq \text{Int}_d(1^v) + \sum_{i=1}^{k-1} (\text{Int}_d(1^v) \setminus \{v/3\}).$$

Proof. For $1 \leq i \leq k$, let $\mathcal{D}_i = (X_i \cup \{\infty\}, \mathcal{G}_i, \mathcal{A}_i)$ and $\mathcal{D}'_i = (X_i \cup \{\infty\}, \mathcal{G}_i, \mathcal{A}'_i)$ be a pair of $\{3\}$ -GDDs of type 1^v intersecting in m_i pairwise disjoint blocks, where $m_1 \in \text{Int}_d(1^v)$ and $m_i \in \text{Int}_d(1^v) \setminus \{v/3\}$ for $2 \leq i \leq k$. We may assume that the point ∞ is not contained in any blocks in the intersection of $\mathcal{D}_i$ and $\mathcal{D}'_i$, $2 \leq i \leq k$.

Let $\mathcal{E} = (\cup_{i=1}^k X_i, \{X_i \mid 1 \leq i \leq k\}, \mathcal{B})$ and $\mathcal{E}' = (\cup_{i=1}^k X_i, \{X_i \mid 1 \leq i \leq k\}, \mathcal{B}')$ be a pair of disjoint $\{3\}$ -GDDs of type $(v-1)^k$, which exists by Theorem 1.1. Let $\mathcal{F} = (\{\infty\}, \emptyset)$. Now apply the Singular Direct Product construction to obtain $\mathcal{D}_1^* = \text{SDP}(\{\mathcal{D}_1, \dots, \mathcal{D}_k\}, \mathcal{E}, \mathcal{F})$ and $\mathcal{D}_2^* = \text{SDP}(\{\mathcal{D}'_1, \dots, \mathcal{D}'_k\}, \mathcal{E}', \mathcal{F})$. It is easy to see that the intersection of $\mathcal{D}_1^*$ and $\mathcal{D}_2^*$ is $\cup_{i=1}^k (A_i \cap A'_i)$, which contains $\sum_{i=1}^k m_i$ pairwise disjoint blocks. $\square$

Lemma 4.2 *Let s and t be positive integers, $t \geq 3$. Then*

$$\text{Int}_d(1^{6st+1}) \supseteq \sum_{i=1}^t \text{Int}_d(1^{6s+1}).$$

Proof. For $1 \leq i \leq t$, let $\mathcal{D}_i = (X_i \cup \{\infty\}, \mathcal{G}_i, \mathcal{A}_i)$ and $\mathcal{D}'_i = (X_i \cup \{\infty\}, \mathcal{G}_i, \mathcal{A}'_i)$ be a pair of $\{3\}$ -GDDs of type 1^{6s+1} intersecting in m_i pairwise disjoint blocks, where $m_i \in \text{Int}_d(1^{6s+1})$. We may assume that the point ∞ is not contained in any of the intersections.

Let $\mathcal{E} = (\cup_{i=1}^t X_i, \{X_i \mid 1 \leq i \leq t\}, \mathcal{B})$ and $\mathcal{E}' = (\cup_{i=1}^t X_i, \{X_i \mid 1 \leq i \leq t\}, \mathcal{B}')$ be a pair of disjoint $\{3\}$ -GDD of type $(6s)^t$, which exists by Theorem 1.1. Let $\mathcal{F} = (\{\infty\}, \emptyset)$. Now apply the Singular Direct Product construction to obtain two $\{3\}$ -GDDs of type 1^{6st+1} $\mathcal{D}_1^* = \text{SDP}(\{\mathcal{D}_i \mid 1 \leq i \leq t\}, \mathcal{E}, \mathcal{F})$ and $\mathcal{D}_2^* = \text{SDP}(\{\mathcal{D}'_i \mid 1 \leq i \leq t\}, \mathcal{E}', \mathcal{F})$. It is easy to see that the intersection of $\mathcal{D}_1^*$ and $\mathcal{D}_2^*$ is $\cup_{i=1}^t (\mathcal{A}_i \cap \mathcal{A}'_i)$, which contains $\sum_{i=1}^t m_i$ pairwise disjoint blocks. $\square$

Lemma 4.3 *Let r, s, t be positive integers such that $t \geq 3$, $r \leq s(t-1)$, and $s^2 \binom{t}{2} + str \equiv 0 \pmod{3}$. Then*

$$\text{Int}_d(1^{6st+6r+1}) \supseteq \text{Int}_d(1^{6r+1}) + \sum_{i=1}^t \text{Int}_d(1^{6s+1}).$$

Proof. For $1 \leq i \leq t$, let $\mathcal{D}_i = (X_i \cup \{\infty\}, \mathcal{G}_i, \mathcal{A}_i)$ and $\mathcal{D}'_i = (X_i \cup \{\infty\}, \mathcal{G}_i, \mathcal{A}'_i)$ be a pair of $\{3\}$ -GDDs of type 1^{6s+1} intersecting in m_i pairwise disjoint blocks, where $m_i \in \text{Int}_d(1^{6s+1})$. We may assume that the point ∞ is not contained in any of the intersections. Let $\mathcal{D}_{t+1} = (X_{t+1} \cup \{\infty\}, \mathcal{G}_i, \mathcal{A}_{t+1})$ and $\mathcal{D}'_{t+1} = (X_{t+1} \cup \{\infty\}, \mathcal{G}_i, \mathcal{A}'_{t+1})$ be a pair of $\{3\}$ -GDDs of type 1^{6r+1} intersecting in m_{t+1} pairwise disjoint blocks, where $m_{t+1} \in \text{Int}_d(1^{6r+1})$.

Let $\mathcal{E} = (\cup_{i=1}^{t+1} X_i, \{X_i \mid 1 \leq i \leq t+1\}, \mathcal{B})$ and $\mathcal{E}' = (\cup_{i=1}^{t+1} X_i, \{X_i \mid 1 \leq i \leq t+1\}, \mathcal{B}')$ be a pair of disjoint $\{3\}$ -GDDs of type $(6s)^t(6r)^1$, which exists by Corollary 3.1. Let $\mathcal{F} = (\{\infty\}, \emptyset)$. Now apply the Singular Direct Product construction to obtain two $\{3\}$ -GDDs of type $1^{6st+6r+1}$ $\mathcal{D}_1^* = \text{SDP}(\{\mathcal{D}_i \mid 1 \leq i \leq t+1\}, \mathcal{E}, \mathcal{F})$ and $\mathcal{D}_2^* = \text{SDP}(\{\mathcal{D}'_i \mid 1 \leq i \leq t+1\}, \mathcal{E}', \mathcal{F})$. It is easy to see that the intersection of $\mathcal{D}_1^*$ and $\mathcal{D}_2^*$ is $\cup_{i=1}^{t+1} (\mathcal{A}_i \cap \mathcal{A}'_i)$, which contains $\sum_{i=1}^{t+1} m_i$ pairwise disjoint blocks. $\square$

5 Direct Constructions

In this section, we determine $\text{Int}_d(1^v)$ for some small values of v .

Lemma 5.1 *The following equalities hold:*

- (i) $\text{Int}_d(1^1) = \{0\}$;
- (ii) $\text{Int}_d(1^3) = \{1\}$;
- (iii) $\text{Int}_d(1^7) = \{0, 1\}$;
- (iv) $\text{Int}_d(1^9) = \{0, 1, 3\}$; and
- (v) for $v \equiv 1, 3 \pmod{6}$, $13 \leq v \leq 31$, $\text{Int}_d(1^v) = \mathcal{I}_d(1^v)$.

5.1 Proof of Lemma 5.1

(i) and (ii) hold trivially and recall that $0, 1 \in \text{Int}_d(1^v)$ for $v \equiv 1, 3 \pmod{6}$, $v \geq 7$. For $7 \leq v \leq 31$, we have the following table.

v	Elements in $\text{Int}_d(1^v)$	Authority
7	0, 1	Trivial

Let $\mathcal{S}_v$, $v \in \{13, 15, 19, 21, 25, 27, 31\}$ be the STS(v)'s given in Appendix A. For an STS(v) $\mathcal{S}_v = (X, \mathcal{B})$ and a permutation $\pi : X \rightarrow X$, π acts on $\mathcal{S}_v$ by canonical extension as follows: $\pi(\mathcal{S}_v) = \{\{\pi(a), \pi(b), \pi(c)\} \mid \{a, b, c\} \in \mathcal{B}\}$. The permutations π listed below is such that $\mathcal{S}_v$ and $\pi(\mathcal{S}_v)$ intersect in m pairwise disjoint blocks, where m is a number whose membership in $\text{Int}_d(1^v)$ has not been established in the table above.

v	<i>Elements in $\text{Int}_d(1^v)$</i>	π

25	6	(0 o 6 3)(1 4 9 j 5 g k 2 l d)(7 h n e)(8 m)(a c i f b)

Any two blocks of an STS(7) intersect in a point. So $2 \notin \text{Int}_d(1^7)$. In an STS(9) $(X, \mathcal{B})$, if $A, B \in \mathcal{B}$ and $A \cap B = \emptyset$, then $X \setminus (A \cup B)$ is a block in $\mathcal{B}$. So $2 \notin \text{Int}_d(1^9)$. For each of the remaining possible disjoint intersection size $m \in \text{Int}_d(1^v)$, we exhibit an STS(v) $\mathcal{D}_v$, listed in Appendix B, whose intersection with $\mathcal{S}_v$ contains m pairwise disjoint blocks.

6 Piecing Things Together

We first deal with the easier case of $v \equiv 3 \pmod{6}$.

6.1 The Case $v \equiv 3 \pmod{6}$

6.1.1 $v \equiv 3 \pmod{18}$

By Theorem 1.1, there exists a pair of disjoint $\{3\}$ -GDDs of type 13^3 . Corollary 3.2 then gives $\text{Int}_d(1^{39}) \supseteq \sum_{i=1}^3 \text{Int}_d(1^{13}) = \sum_{i=1}^3 \{0, \dots, 4\} = \{0, \dots, 12\}$. By Theorem 1.1, there also exists a pair of disjoint $\{3\}$ -GDDs of type 3^{13} . Corollary 3.2 now gives $\text{Int}_d(1^{39}) \supset \sum_{i=1}^{13} \text{Int}_d(1^3) = \sum_{i=1}^{13} \{1\} = \{13\}$. Hence $\text{Int}_d(1^{39}) = \mathcal{I}_d(1^{39})$.

For $v \geq 57$, consider a pair of disjoint $\{3\}$ -GDDs of type $9^t 21^1$, where $t = (v - 21)/9$, existence of which is provided by Corollary 3.1. Now apply Corollary 3.2 to obtain

$$\begin{aligned}
\text{Int}_d(1^v) &\supseteq \text{Int}_d(1^{21}) + \sum_{i=1}^t \text{Int}_d(1^9) \\
&= \{0, \dots, 7\} + \sum_{i=1}^t \{0, 1, 3\} \\
&= \{0, \dots, 3t + 7\} \\
&= \mathcal{I}_d(1^v).
\end{aligned}$$

This establishes the following.

Lemma 6.1 $\text{Int}_d(1^v) = \mathcal{I}_d(1^v)$ for $v \equiv 3 \pmod{18}$, $v \geq 39$.

6.1.2 $v \equiv 9 \pmod{18}$

By Theorem 1.1, there exists a pair of disjoint $\{3\}$ -GDDs of type 15^3 . Corollary 3.2 then gives $\text{Int}_d(1^{45}) \supseteq \sum_{i=1}^3 \text{Int}_d(1^{15}) = \sum_{i=1}^3 \{0, \dots, 5\} = \{0, \dots, 15\} = \mathcal{I}_d(1^{45})$.

For $v \geq 63$, consider a pair of disjoint $\{3\}$ -GDDs of type $9^t 27^1$, where $t = (v - 27)/9$, existence of which is provided by Corollary 3.1. Now apply Corollary 3.2 to obtain

$$\begin{aligned}
\text{Int}_d(1^v) &\supseteq \text{Int}_d(1^{27}) + \sum_{i=1}^t \text{Int}_d(1^9) \\
&= \{0, \dots, 9\} + \sum_{i=1}^t \{0, 1, 3\} \\
&= \{0, \dots, 3t + 9\} \\
&= \mathcal{I}_d(1^v).
\end{aligned}$$

This establishes the following.

Lemma 6.2 $\text{Int}_d(1^v) = \mathcal{I}_d(1^v)$ for $v \equiv 9 \pmod{18}$, $v \geq 45$.

6.1.3 $v \equiv 15 \pmod{18}$

By Corollary 3.1, there exists a pair of disjoint $\{3\}$ -GDDs of type $3^6 15^1$. Corollary 3.2 then gives $\text{Int}_d(1^{33}) \supseteq \text{Int}_d(1^{15}) + \sum_{i=1}^6 \text{Int}_d(1^3) = \{0, \dots, 5\} + \{6\} = \{6, \dots, 11\}$. Also, by Lemma 4.1, we have $\text{Int}_d(1^{33}) \supseteq \text{Int}_d(1^9) + \sum_{i=1}^3 (\text{Int}_d(1^9) \setminus \{3\}) = \{0, 1, 3\} + \sum_{i=1}^3 \{0, 1\} = \{0, 1, 2, 3, 4, 5, 6\}$. Hence we have $\text{Int}_d(1^{33}) = \mathcal{I}_d(1^{33})$.

For $v \geq 51$, consider a pair of disjoint $\{3\}$ -GDDs of type $9^t 15^1$, where $t = (v - 15)/9$, whose existence is provided by Corollary 3.1. Now apply Corollary 3.2 to obtain

$$\begin{aligned}
\text{Int}_d(1^v) &\supseteq \text{Int}_d(1^{15}) + \sum_{i=1}^t \text{Int}_d(1^9) \\
&= \{0, \dots, 5\} + \sum_{i=1}^t \{0, 1, 3\} \\
&= \{0, \dots, 3t + 5\} \\
&= \mathcal{I}_d(1^v).
\end{aligned}$$

This establishes the following.

Lemma 6.3 $\text{Int}_d(1^v) = \mathcal{I}_d(1^v)$ for $v \equiv 15 \pmod{18}$, $v \geq 33$.

6.2 The Case $v \equiv 1 \pmod{6}$

6.2.1 $v \equiv 1 \pmod{18}$

Let $s = 2$, $t = 3$. Then Lemma 4.2 gives $\text{Int}_d(1^{37}) \supseteq \sum_{i=1}^3 \text{Int}_d(1^{13}) = \sum_{i=1}^3 \{0, \dots, 4\} = \{0, \dots, 12\} = \mathcal{I}_d(1^{37})$.

For $v \geq 55$, let $s = 3$, $t = (v - 1)/18$. Now apply Lemma 4.2 to obtain

$$\begin{aligned}
\text{Int}_d(1^v) &\supseteq \sum_{i=1}^t \text{Int}_d(1^{19}) \\
&= \sum_{i=1}^t \{0, \dots, 6\} \\
&= \{0, \dots, 6t\} \\
&= \mathcal{I}_d(1^v).
\end{aligned}$$

This establishes the following.

Lemma 6.4 $\text{Int}_d(1^v) = \mathcal{I}_d(1^v)$ for $v \equiv 1 \pmod{18}$, $v \geq 37$.

6.2.2 $v \equiv 7 \pmod{18}$

Let $v \geq 43$. Let $w = (v + 2)/3$. Then $w \equiv 3 \pmod{6}$ and $w \geq 15$. Now apply Corollary 4.1 to obtain

$$\begin{aligned}
\text{Int}_d(1^v) &\supseteq \text{Int}_d(1^w) + (\text{Int}_d(1^w) \setminus \{w/3\}) + (\text{Int}_d(1^w) \setminus \{w/3\}) \\
&= \{0, \dots, w/3\} + \{0, \dots, w/3 - 1\} + \{0, \dots, w/3 - 1\} \\
&= \{0, \dots, w - 2\} \\
&= \{0, \dots, (v - 1)/3 - 1\}.
\end{aligned}$$

To show that $(v-1)/3 \in \text{Int}_d(1^v)$, mimic the proof of Lemma 4.1 but with $m_1 = m_2 = m_3 = 0$ and replace the ingredient $\{3\}$ -GDD of type $(w-1)^3$ with a pair of $\{3\}$ -GDDs of type $(w-1)^3$ intersecting in $w-1$ disjoint blocks, existence of which is provided by Corollary 2.1. This establishes the following.

Lemma 6.5 $\text{Int}_d(1^v) = \mathcal{I}_d(1^v)$ for $v \equiv 7 \pmod{18}$, $v \geq 43$.

6.2.3 $v \equiv 13 \pmod{18}$

Let $s = 2$ and $t = 4$. Then Lemma 4.2 gives $\text{Int}_d(1^{49}) \supseteq \sum_{i=1}^4 \text{Int}_d(1^{13}) = \sum_{i=1}^4 \{0, \dots, 4\} = \{0, \dots, 16\} = \mathcal{I}_d(1^{49})$.

For $v \geq 67$, let $t = (v-13)/18$. Then $t \geq 3$. Now apply Corollary 4.3 with $r = 2$ and $s = 3$ to obtain

$$\begin{aligned} \text{Int}_d(1^v) &= \text{Int}_d(1^{18t+13}) \\ &\supseteq \text{Int}_d(1^{13}) + \sum_{i=1}^t \text{Int}_d(1^{19}) \\ &= \{0, \dots, 4\} + \sum_{i=1}^t \{0, \dots, 6\} \\ &= \{0, \dots, 6t+4\} \\ &= \mathcal{I}_d(1^v). \end{aligned}$$

This establishes the following.

Lemma 6.6 $\text{Int}_d(1^v) = \mathcal{I}_d(1^v)$ for $v \equiv 13 \pmod{18}$, $v \geq 49$.

7 Conclusion

Lemmas 6.1 to 6.6 shows that $\text{Int}_d(1^v) = \mathcal{I}_d(1^v)$ for all $v \equiv 1, 3 \pmod{6}$, $v \geq 33$. Lemma 5.1 gives $\text{Int}_d(1^v)$ for all $v \equiv 1, 3 \pmod{6}$, $v \leq 31$. This combines to give the main result of this paper below.

Theorem 7.1 *Let $v \equiv 1, 3 \pmod{6}$. Then $\text{Int}_d(1^v) = \mathcal{I}_d(1^v)$, except that*

- (i) $\text{Int}_d(1^7) = \{0, 1\}$; and
- (ii) $\text{Int}_d(1^9) = \{0, 1, 3\}$.

If there exists a pair of $\text{STS}(v)$ intersecting in t pairwise disjoint blocks, we can consider these t pairwise disjoint blocks as groups of a pair of disjoint $\{3\}$ -GDDs of type $3^t 1^{v-t}$, and vice versa. Hence, Theorem 7.1 is equivalent to the following.

Theorem 7.2 *Let $3t+r \equiv 1, 3 \pmod{6}$, $3t+r \geq 13$. Then there exists a pair of disjoint $\{3\}$ -GDDs of type $3^t 1^r$.*
