Abstract

The importance of Pfaffian orientations stems from the fact that if a graph G is Pfaffian, then the number of perfect matchings of G (as well as other related problems) can be computed in polynomial time. Although there are many equivalent conditions for the existence of a Pfaffian orientation of a graph, this property is not well-characterized. The problem is that no polynomial algorithm is known for checking whether or not a given orientation of a graph is Pfaffian. Similarly, we do not know whether this property of an undirected graph that it has a Pfaffian orientation is in NP. It is well known that the enumeration problem of perfect matchings for general graphs is NP-hard. L. Lovász pointed out that it makes sense not only to seek good upper and lower bounds of the number of perfect matchings for general graphs, but also to seek special classes for which the problem can be solved exactly. For a simple graph G and a cycle C_n with n vertices (or a path P_n with n vertices), we define C_n (or P_n) $\times G$ as the Cartesian product of graphs C_n (or P_n) and G . In the present paper, we construct Pfaffian orientations of graphs $C_4 \times G$, $P_4 \times G$ and $P_3 \times G$, where G is a non bipartite graph with a unique cycle, and obtain the explicit formulas in terms of eigenvalues of the skew adjacency matrix of $\vec{G}$ to enumerate their perfect matchings by Pfaffian approach, where $\vec{G}$ is an arbitrary orientation of G .

1. Introduction

The theory of Pfaffian orientations of graphs had been introduced by the physicists M. E. Fisher, P. W. Kasteleyn, and H. N. V. Temperley. The importance of Pfaffian orientations stems

*This work is supposed by NFSC (NO.10831001).

[†]Corresponding author.

from the fact that if a graph G is Pfaffian, then the number of perfect matchings of G (as well as other related problems) can be computed in polynomial time.

P. W. Kasteleyn gave a polynomial time algorithm for computing the number of perfect matchings in planar graphs using Pfaffian method and extended his approach to toroidal grids in [6] and [8]. Litte [9] generalized P. W. Kasteleyn's work and proved that if a bipartite graph G contains no subdivision of $K_{3,3}$, then G has a Pfaffian orientation. Furthermore, Fischer and Little [3] proved that a graph has a Pfaffian orientation under which every cycle of even length is clockwise odd if and only if the graph contains no subgraph which is, after the contraction of at most one cycle of odd length, an even subdivision of $K_{2,3}$. McCuaig [11], and McCuaig, Robertson et al [12], and Robertson, Seymour et al [15] found a polynomial-time algorithm to determine whether a bipartite graph has a Pfaffian orientation respectively. In spite of there are many equivalent conditions for the existence of a Pfaffian orientation of a graph, this property is not well-characterized. The problem is that no polynomial algorithm is known for checking whether or not a given orientation of a graph G is Pfaffian. We do not even know whether this property is in NP. (It is trivially in co-NP; to prove that a given orientation is non-Pfaffian, it suffices to exhibit two perfect matchings with different signs.) similarly, we do not know whether the property of an undirected graph that it has a Pfaffian orientation is in NP.

The number of perfect matchings is an important topological index which has been applied for estimation of the resonant energy and total π -electron energy and calculation of pauling bond order (see [4], [13], [16]). Enumeration problem for perfect matchings in general graphs (even in bipartite graph) is NP-hard. L. Lovász [10] pointed out that it makes sense not only to seek good upper and lower bounds of the number of perfect matchings for general graphs, but also to seek special classes for which the problem can be solved exactly. So far, many mathematicians, physicists and chemists have focused most of their attention on the enumeration problem for perfect matchings (see [2], [3], [5], [14], [15]).

First, we repeat some standard definitions. A graph G is a pair $V(G)$ and $E(G)$, where $V(G)$ is a finite set of vertices and $E(G)$ is a set of unordered pairs xy of vertices called edges. We say that the edge xy is incident with x, y and that x, y are adjacent and are called the ends of the edge xy . All graphs in this paper are simple graphs which are finite, do not have loops or multiple edges. A graph H is a subgraph of G if $V(H) \subseteq V(G)$ and $E(H) \subseteq E(G)$. A spanning subgraph of G is a subgraph H with $V(H) = V(G)$. For a nonempty subset V' of $V(G)$, a subgraph of G is called induced subgraph induced by V' if its vertex set is V' and edge set is the set of those edges of G that have both ends in V' . A k -path denoted by $x_0x_1 \dots x_k$ is the graph with distinct vertices $x_0, x_1, \dots, x_k$ and edges $x_{i-1}x_i$, $i = 1, 2, \dots, k$, where x_0, x_k are called its ends. A k -cycle is obtained from a $(k - 1)$ -path by adding the edge between the two ends x_0, x_{k-1} . We say that k is the length of the k -path and k -cycle. A path and a cycle with n vertices are denoted by P_n and C_n respectively. A graph is connected if any two vertices are joined by a path. A bipartite graph is one whose vertex set can be partitioned into two disjoint subsets X and Y , so that each edge has one end in X and one end in Y ; such a partition (X, Y) is called a bipartition of the graph. A graph is bipartite if and only if each cycle of it has even length. A tree is a connected acyclic graph. Clearly, a tree is bipartite. A perfect matching of a simple graph G is a set of vertex-disjoint edges that are collectively incident to all vertices. A cycle C of G is said to be

nice if $G - C$ contains a perfect matching, where $G - C$ denotes the induced subgraph of G obtained from G by deleting the vertices of C . If C is a nice cycle of a spanning subgraph of G , then C is also a nice cycle of G . Let $\vec{G}$ denote an orientation of G which is obtained from G by specifying, for each edge, an orientation on its ends. If C is an even undirected cycle in $\vec{G}$, we shall say C is evenly oriented if it has an even number of edges oriented in the direction of the routing. Otherwise C is oddly oriented. An orientation $\vec{G}$ is Pfaffian if every nice cycle of G is oddly oriented in $\vec{G}$. A graph G is Pfaffian if it has a Pfaffian orientation.

For $V(G) = \{v_1, v_2, \dots, v_n\}$, the skew adjacency matrix of $\vec{G}$, denoted by $A(\vec{G})$, is defined as follows:

$$A(\vec{G}) = (a_{ij})_{n \times n}, \quad \text{where} \quad a_{ij} = \begin{cases} 1 & \text{if } (v_i, v_j) \in E(\vec{G}), \\ -1 & \text{if } (v_j, v_i) \in E(\vec{G}), \\ 0 & \text{otherwise.} \end{cases}$$

Let $\overleftarrow{G}$ be the reverse orientation of $\vec{G}$ such that $A(\overleftarrow{G}) = -A(\vec{G})$.

The cartesian product of two graphs G and H denoted by $G \times H$ is the graph with vertex set $V(G) \times V(H)$ such that (x, u) and (y, v) are adjacent iff either $x = y$ and u and v are adjacent in H , or $u = v$ and x and y are adjacent in G . For bipartite graphs, Yan and Zhang in [18] studied the enumeration of perfect matchings for these Cartesian product of graphs $C_4 \times T$, $P_4 \times T$ and $P_3 \times T$, where T is a tree. In the present paper, we construct Pfaffian orientations of some Cartesian product of graphs which are non-bipartite and obtain explicit formulas to enumerate their perfect matchings by Pfaffian approach as follows.

$$(1) \phi(C_4 \times G) = \prod_{\lambda \in \lambda(\vec{G})} (2 - \lambda^2); \quad (2) \phi(P_4 \times G) = \prod_{\lambda \in \lambda^*(\vec{G})} (1 - 3\lambda^2 + \lambda^4);$$

$$(3) \text{ If } G \text{ has a perfect matching, then } \phi(P_3 \times G) = \prod_{\lambda \in \lambda^*(\vec{G})} (2 - \lambda^2) \text{ and } \phi(C_4 \times G) = \phi(P_3 \times G)^2,$$

where G is a non-bipartite graph with a unique cycle, $\vec{G}$ is an arbitrary orientation of G , $\lambda(\vec{G})$ is the set of all eigenvalues of $A(\vec{G})$ and $\lambda^*(\vec{G})$ is the set of those non-negative imaginary part eigenvalues of $A(\vec{G})$.

2. Pfaffian orientation

Theorem 2.1 [10]. *Let G be any simple graph with even number of vertices, and $\vec{G}$ be an orientation of G . Then the following three properties are equivalent:*

- (1) $\vec{G}$ is a Pfaffian orientation.
- (2) Every nice cycle in G is oddly oriented relative to $\vec{G}$.
- (3) If G has a perfect matching, then for some perfect matching F , every F -alternating cycle is oddly oriented relative to $\vec{G}$.

For a simple graph G with $V(G) = \{v_1, v_2, \dots, v_n\}$, let G_1 and G_2 be two copies of G with $V(G_1) = \{v'_1, v'_2, \dots, v'_n\}$ and $V(G_2) = \{v''_1, v''_2, \dots, v''_n\}$ respectively, where v'_i in G_1 and v''_i

in G_2 are corresponding to v_i in G ($i = 1, 2, \dots, n$). Adding the edges $v'_i v''_i$ ($i = 1, 2, \dots, n$) between G_1 and G_2 , the resulting graph is $P_2 \times G$ with vertex set $V(G_1) \cup V(G_2)$ and edge set $E(G_1) \cup E(G_2) \cup \{v'_i v''_i \mid i = 1, 2, \dots, n\}$. If $\vec{G}$ is an orientation of G , then we denote the orientation of $P_2 \times G$ by $(P_2 \times \vec{G})^e$ which is defined as follows: the orientation of G_1 (the left half of $P_2 \times G$) is the same as $\vec{G}$ and that of G_2 (the right half of $P_2 \times G$) is the same as $\overleftarrow{G}$, and the orientations of edges $v'_i v''_i$ ($i = 1, 2, \dots, n$) are from v'_i to v''_i (see Figure 1).

Figure 1.

Lemma 2.2 [17]. Let G be a simple graph. If $\vec{G}$ is an orientation of G under which every cycle of even length is oddly oriented in $\vec{G}$, then the orientation $(P_2 \times \vec{G})^e$ is a Pfaffian orientation of $P_2 \times G$.

Lemma 2.3 [18]. Suppose G is a tree with $V(G) = \{v_1, v_2, \dots, v_n\}$. Then every cycle C of $P_2 \times G$ is a nice cycle and can be written as:

$$v'_1 v'_2 \dots v'_m v''_m v''_{m-1} \dots v''_2 v''_1 v'_1, \quad (1)$$

where $i_1, i_2, \dots, i_m \in \{1, 2, \dots, n\}$.

Lemma 2.4. If G is a tree with $V(G) = \{v_1, v_2, \dots, v_n\}$, then any two paths $P_{v'_i - v'_j}$ and $P_{v'_j - v'_i}$ for $i \neq j$ must intersect each other in $P_2 \times G$, $i, j \in \{1, 2, \dots, n\}$.

Proof. We prove this assertion by contradiction. If there exist two disjoint paths $P_{v'_i - v'_j}$ and $P_{v'_j - v'_i}$ for $i \neq j$ in $P_2 \times G$, then there is a cycle of $P_2 \times G$ that consists of $P_{v'_i - v'_j}$, $v'_j v'_i$, $P_{v'_j - v'_i}$ and $v''_i v''_j$, which has the following form:

$$v'_i \dots v'_j v'_j v''_j \dots v''_i v''_i. \quad (2)$$

In the other hand, by Lemma 2.3, every cycle of $P_2 \times G$ has the form (1) in Lemma 2.3. It is clear that the cycle form (2) is distinct from the cycle form (1), a contradiction. The assertion holds. $\square$

In order to formulate our main results, it is necessary to introduce further terminology.

Suppose G is a non-bipartite graph with a unique cycle. For convenience, let C^* denote the unique odd cycle of G with length $2k + 1$, and label the vertices of G as $v_1, v_2, \dots, v_{2k+1}, \dots, v_n$ such that $C^* = v_1 v_2 \dots v_{2k+1} v_1$ (see Figure 2(a)). In $P_2 \times G$ (see Figure 2(b)), let the cycles C_i^* in G_i ($i=1, 2$) be corresponding to the cycle C^* in G . For $E' \subseteq E(G)$, $G - E'$ denotes the graph obtained from G by deleting the edges in E' . If $E' = \{e\}$ we write $G - e$ instead of $G - \{e\}$. A path with ends s and t is denoted by P_{s-t} .

Figure 2.

Theorem 2.5. *If G is a non-bipartite graph with a unique cycle, then every even cycle of $P_2 \times G$ is a nice cycle of it.*

Proof. We only need to prove the case that G is a connected graph. Suppose $\tilde{C}$ is an even cycle in $P_2 \times G$, and $E' = \{v'_1v'_{2k+1}, v''_1v''_{2k+1}\}$. If $\tilde{C}$ contains no edge of E' , then $\tilde{C}$ is an even cycle of $P_2 \times (G - v_1v_{2k+1})$ (see Figure 2(c)) which is a spanning subgraph of $P_2 \times G$. Since $G - v_1v_{2k+1}$ is a tree, $\tilde{C}$ is a nice cycle of $P_2 \times (G - v_1v_{2k+1})$ by Lemma 2.3. Thus $\tilde{C}$ is a nice cycle of $P_2 \times G$.

If $\tilde{C}$ contains exactly one edge of E' , without loss of generality, we assume that $\tilde{C}$ contains the edge $v'_1v'_{2k+1}$. Since $G - v_1v_{2k+1}$ is a tree, it is bipartite. If (V_1, V_2) is its a bipartition, then $P_2 \times (G - v_1v_{2k+1})$ is a bipartite graph with a bipartition $(V'_1 \cup V'_2, V''_1 \cup V''_2)$, where both V'_i and V''_i are corresponding to V_i , $i = 1, 2$. Furthermore, there exists a $2k$ -path $v'_1v'_2 \dots v'_iv'_{i+1} \dots v'_{2k}v'_{2k+1}$, so the two vertices v'_1, v'_{2k+1} belong to the same partitioned subset. Hence $\tilde{C} - v'_1v'_{2k+1}$ is a path $P_{v'_1-v'_{2k+1}}$ of $P_2 \times (G - v_1v_{2k+1})$ which always has even length. Thus the length of $\tilde{C}$ is odd, a contradiction.

If $\tilde{C}$ contains both edges of E' , then $\tilde{C} - E'$ consists of two disjoint paths $P_{v'_1-v''_1}$ and $P_{v'_{2k+1}-v''_{2k+1}}$ of $P_2 \times (G - v_1v_{2k+1})$. Otherwise, there are two disjoint paths $P_{v'_1-v''_{2k+1}}$ and $P_{v'_{2k+1}-v''_1}$ which contradicts to Lemma 2.4. By application of Lemma 2.3, we have $P_{v'_1-v''_1} = v'_1v''_1$ or $v'_1v'_{i_1} \dots v'_{i_s}v''_{i_s} \dots v''_{i_1}v'_1$, and $P_{v'_{2k+1}-v''_{2k+1}} = v'_{2k+1}v''_{2k+1}$ or $v'_{2k+1}v'_{j_1} \dots v'_{j_t}v''_{j_t} \dots v''_{j_1}v'_{2k+1}$ respectively. Thus, $\{v'_lv''_l \mid 1 \leq l \leq n, v'_l \notin V(\tilde{C})\}$ is a perfect matching of $G - \tilde{C}$. Therefore $\tilde{C}$ is a nice cycle. $\square$

By Theorem 2.5, the following corollary is immediate.

Corollary 2.6. *Every even cycle of $P_2 \times C_{2k+1}$ is a nice cycle of it.*

Suppose G is a non-bipartite graph with a unique cycle and $\vec{G}$ is an arbitrary orientation of G . By Lemma 2.2, the orientation $(P_2 \times \vec{G})^e$ is a Pfaffian orientation of $P_2 \times G$. Hence every nice cycle in $(P_2 \times \vec{G})^e$ is oddly oriented by Theorem 2.1. By Theorem 2.5, the orientation $(P_2 \times \vec{G})^e$ is an orientation of $P_2 \times G$ under which every even cycle of $P_2 \times G$ is oddly oriented. Now we apply Lemma 2.2 with G replaced by $P_2 \times G$, then $(P_2 \times (P_2 \times \vec{G})^e)^e$ is a Pfaffian orientation of $P_2 \times (P_2 \times G)$. Since $P_2 \times P_2 = C_4$, we use $(C_4 \times \vec{G})^e$ instead of $(P_2 \times (P_2 \times \vec{G})^e)^e$ for convenience. Figure 3 illustrates the orientation procedure.

Figure 3.

For G with $V(G) = \{v_1, v_2, \dots, v_n\}$, take m copies of G , denoted by G_i with $V(G_i) = \{v_1^{(i)}, v_2^{(i)}, \dots, v_n^{(i)}\}$, $i = 1, 2, \dots, m$. $P_m \times G$ is the graph with vertex set $\bigcup_{j=1}^m V(G_i)$ and edge set $\bigcup_{j=1}^m E(G_i) \cup \{v_j^{(i)} v_j^{(i+1)} | 1 \leq j \leq n, 1 \leq i \leq m-1\}$. Let $\vec{G}$ be an orientation of G . We define the orientation of G_i in $P_m \times G$ to be the same as $\vec{G}$ if i is odd, $\overleftarrow{\vec{G}}$ otherwise, and the orientations of edges $v_j^{(i)} v_j^{(i+1)}$ in $P_m \times G$ to be from $v_j^{(i)}$ to $v_j^{(i+1)}$ ($1 \leq j \leq n, 1 \leq i \leq m-1$). The orientation of $P_m \times G$ defined as above is denoted by $(P_m \times \vec{G})^e$. The processes of the orientations $(P_3 \times \vec{G})^e$ and $(P_4 \times \vec{G})^e$ are shown in Figure 4.

Figure 4.

Since $P_4 \times G$ is a spanning subgraph of $C_4 \times G$, every nice cycle in $P_4 \times G$ is also a nice cycle in $C_4 \times G$. Noting that $(P_4 \times \vec{G})^e$ is the orientation $(C_4 \times \vec{G})^e$ restricted in $P_4 \times G$ and $(C_4 \times \vec{G})^e$ is a Pfaffian orientation, we obtain that every nice cycle in $P_4 \times G$ is oddly oriented relative to $(P_4 \times \vec{G})^e$. Then we get the following theorem immediately.

Theorem 2.7. *Let G be a non-bipartite graph with a unique cycle, and $\vec{G}$ be an arbitrary orientation of G . Then the orientations $(C_4 \times \vec{G})^e$ of $C_4 \times G$ and $(P_4 \times \vec{G})^e$ of $P_4 \times G$ are Pfaffian orientations.*

Theorem 2.8. *Let G be a non-bipartite graph with a unique cycle, and $\vec{G}$ be an arbitrary orientation of G . If G has a perfect matching, then $(P_3 \times \vec{G})^e$ is a Pfaffian orientation of $P_3 \times G$.*

Proof. Since G has a perfect matching, it is clear that $P_3 \times G$ has a perfect matching. Suppose C is an arbitrary nice cycle of $P_3 \times G$ and M_1 is a perfect matching of $P_3 \times G - C$. Let M_2 be a perfect matching of G_4 in $P_4 \times G$. Clearly $M_1 \cup M_2$ is a perfect matching of $P_4 \times G - C$. So that every nice cycle in $P_3 \times G$ is also a nice cycle in $P_4 \times G$. Moreover, $(P_3 \times \vec{G})^e$ is the orientation $(P_4 \times \vec{G})^e$ restricted in $P_3 \times G$, and $(P_4 \times \vec{G})^e$ is a Pfaffian orientation by Theorem 2.7, so every nice cycle in $P_3 \times G$ is oddly oriented relative to $(P_3 \times \vec{G})^e$. By Theorem 2.1, $(P_3 \times \vec{G})^e$ is a Pfaffian orientation. $\square$

3. Enumeration of perfect matchings

If a graph G has a Pfaffian orientation $\vec{G}$, then the number of perfect matchings of G denoted by $\phi(G)$ can be computed in polynomial time by the following theorem.

Theorem 3.1 [7], [8], [10]. Let $\vec{G}$ be a Pfaffian orientation of a graph G . Then

$$\phi(G)^2 = \det A(\vec{G}),$$

where $A(\vec{G})$ is the skew adjacency matrix of $\vec{G}$.

Theorem 3.2. Let G be a non-bipartite graph with a unique cycle, and $\vec{G}$ be an arbitrary orientation of G . Then

$$\phi(C_4 \times G) = \prod_{\lambda \in \lambda(\vec{G})} (2 - \lambda^2),$$

where $\lambda(\vec{G})$ is the set of all eigenvalues of $A(\vec{G})$.

Proof. $(C_4 \times \vec{G})^e$ is a Pfaffian orientation of $C_4 \times G$ by Theorem 2.7. The skew adjacency matrix of $(C_4 \times \vec{G})^e$ has the following form by a suitable labeling of vertices of $(C_4 \times \vec{G})^e$:

$$A((C_4 \times \vec{G})^e) = \begin{pmatrix} A(\vec{G}) & I & I & 0 \\ -I & -A(\vec{G}) & 0 & I \\ -I & 0 & -A(\vec{G}) & -I \\ 0 & -I & I & A(\vec{G}) \end{pmatrix} = \begin{pmatrix} A & B \\ C & D \end{pmatrix},$$

where I is the identity matrix, $A = \begin{pmatrix} A(\vec{G}) & I \\ -I & -A(\vec{G}) \end{pmatrix}$, $B = \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix}$, $C = \begin{pmatrix} -I & 0 \\ 0 & -I \end{pmatrix}$, $D = \begin{pmatrix} -A(\vec{G}) & -I \\ I & A(\vec{G}) \end{pmatrix}$.

It is well known that for four matrixes A, B, C, D with equivalent order n , if $\det A \neq 0$ and $AC = CA$, then $\det \begin{pmatrix} A & B \\ C & D \end{pmatrix} = \det(AD - CB)$. By Theorem 3.1, we have

$$\begin{aligned} \phi(C_4 \times G)^2 &= \det A((C_4 \times \vec{G})^e) \\ &= \det \left\{ - \begin{pmatrix} A(\vec{G}) & I \\ -I & -A(\vec{G}) \end{pmatrix}^2 + \begin{pmatrix} I & 0 \\ 0 & I \end{pmatrix} \right\} \\ &= \det \begin{pmatrix} 2I - (A(\vec{G}))^2 & 0 \\ 0 & 2I - (A(\vec{G}))^2 \end{pmatrix} \\ &= (\det(2I - A(\vec{G})^2))^2. \end{aligned}$$

Since $A(\vec{G})$ is a real skew matrix, its eigenvalues are either zeros or pure imaginary numbers,

hence

$$\phi(C_4 \times G) = \left| \det(2I - A(\vec{G})^2) \right| = \prod_{\lambda \in \lambda(\vec{G})} (2 - \lambda^2),$$

where $\lambda(\vec{G})$ is the set of all eigenvalues of $A(\vec{G})$. □

Corollary 3.3. *Let G be an odd cycle with $2k + 1$ vertices. Then*

$$\phi(C_4 \times G) = \prod_{j=1}^{2k+1} \left(2 + 4 \sin^2 \left(\frac{2j\pi}{2k+1} \right) \right).$$

Proof. Without loss of generality, we orient every edge of the odd cycle G clockwise. Then the skew adjacency matrix $A(\vec{G})$ is a circulant matrix [1], and the eigenvalues of $A(\vec{G})$ are $\lambda_j = 2i \sin(\frac{2j\pi}{2k+1})$, $j = 1, 2, \dots, 2k, 2k+1$. By Theorem 3.2, the assertion holds. □

Remark. Note that the graph $C_m \times C_n$ can be considered as the lattice imbedded on a torus. In this case, the author of paper [6] had presented a rigorous but more complex solution to enumerate its perfect matchings.

Theorem 3.4. *Let G be a non-bipartite graph with a unique cycle, and $\vec{G}$ be an arbitrary orientation of G . Then*

$$\phi(P_4 \times G) = \prod_{\lambda \in \lambda^*(\vec{G})} (1 - 3\lambda^2 + \lambda^4),$$

where $\lambda^*(\vec{G})$ is the set of those non-negative imaginary part eigenvalues of $A(\vec{G})$.

Proof. By Theorem 2.7, $(P_4 \times \vec{G})^e$ is a Pfaffian orientation of $P_4 \times G$. Hence, by Theorem 3.1, we have

$$\phi(P_4 \times G)^2 = \det A((P_4 \times \vec{G})^e).$$

By a suitable labeling of vertices of $(P_4 \times \vec{G})^e$, the skew adjacency matrix of $(P_4 \times \vec{G})^e$ has the following form:

$$A((P_4 \times \vec{G})^e) = \begin{pmatrix} A(\vec{G}) & I & 0 & 0 \\ -I & -A(\vec{G}) & I & 0 \\ 0 & -I & A(\vec{G}) & I \\ 0 & 0 & -I & -A(\vec{G}) \end{pmatrix},$$

Now multiplying the first column, then the third and fourth row, then the fourth column of the partitioned matrix $A((P_4 \times \vec{G})^e)$ by -1 , without changing the absolute value of the determinant we obtain the matrix

$$\begin{aligned} M &= \begin{pmatrix} -A(\vec{G}) & I & 0 & 0 \\ I & -A(\vec{G}) & I & 0 \\ 0 & I & -A(\vec{G}) & I \\ 0 & 0 & I & -A(\vec{G}) \end{pmatrix} \\ &= -I_4 \otimes A(\vec{G}) + B \otimes I_n, \end{aligned}$$

where $\otimes$ denotes the Kronecker product of matrices and

$$B = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix}.$$

It is well known the eigenvalues of $-I_4 \otimes A + B \otimes I_n$ are

$$\mu_i - \lambda_j \quad (1 \leq i \leq 4, \quad 1 \leq j \leq n),$$

where $\lambda_1, \lambda_2, \dots, \lambda_n$ are the eigenvalues of $A(\vec{G})$ and μ_1, μ_2, μ_3 and μ_4 are the eigenvalues of B .

It is easy to calculate that the eigenvalues of B are

$$\pm \sqrt{\frac{3 + \sqrt{5}}{2}}, \quad \pm \sqrt{\frac{3 - \sqrt{5}}{2}}.$$

Thus the eigenvalues of M are

$$\pm \sqrt{\frac{3 + \sqrt{5}}{2}} - \lambda_s, \pm \sqrt{\frac{3 - \sqrt{5}}{2}} - \lambda_s, (s = 1, 2, \dots, n).$$

Since the determinant of the matrix M is the product of these eigenvalues,

$$\begin{aligned} \left| \det(A((P_4 \times \vec{G})^e)) \right| &= |M| \\ &= \left| \prod_{s=1}^n \left(\sqrt{\frac{3 + \sqrt{5}}{2}} - \lambda_s \right) \left(-\sqrt{\frac{3 + \sqrt{5}}{2}} - \lambda_s \right) \left(\sqrt{\frac{3 - \sqrt{5}}{2}} - \lambda_s \right) \left(-\sqrt{\frac{3 - \sqrt{5}}{2}} - \lambda_s \right) \right| \\ &= \prod_{s=1}^n (1 - 3\lambda_s^2 + \lambda_s^4). \end{aligned}$$

If λ is an eigenvalue of the real skew matrix $A(\vec{G})$, so is its conjugate $\bar{\lambda}$. Hence we have

$$\begin{aligned} \phi(P_4 \times G) &= \sqrt{\det(A((P_4 \times \vec{G})^e))} \\ &= \prod_{s=1}^n \sqrt{(1 - 3\lambda_s^2 + \lambda_s^4)} \\ &= \prod_{\lambda \in \lambda^*(\vec{G})} (1 - 3\lambda^2 + \lambda^4), \end{aligned}$$

where $\lambda^*(\vec{G})$ is the set of those non-negative imaginary part eigenvalues of $A(\vec{G})$. The Theorem is proved. $\square$

Similarly, by using Theorem 2.8, we can prove the following Theorem.

Theorem 3.5. *Let G be a non-bipartite graph with a unique cycle, and $\vec{G}$ be an arbitrary orientation of G . If G has a perfect matching, then*

$$\phi(P_3 \times G) = \prod_{\lambda \in \lambda^*(\vec{G})} (2 - \lambda^2),$$

where $\lambda^*(\vec{G})$ is the set of those non-negative imaginary part eigenvalues of $A(\vec{G})$.

Corollary 3.6. *Let G be a non-bipartite graph with a unique cycle, and $\vec{G}$ be an arbitrary orientation of G . If G has a perfect matching, then $\phi(P_3 \times G)^2 = \phi(C_4 \times G)$.*

Proof. Corollary 3.6 is immediate from Theorem 3.2 and 3.5. □

Acknowledgements

We wish to thank Professor Weigen Yan for too much useful help and advice.
