Abstract

Let g_{n_1, n_2} be the number of standard Young tableau of truncated shifted shape with n_1 rows and n_2 boxes in each row. By using the integral method this paper derives the recurrence relations of $g_{3, n}$, $g_{n, 4}$ and $g_{n, 5}$ respectively. Specifically, $g_{n, 4}$ is the $(2n - 1)$ -st Pell number.

Keywords: standard Young tableaux; multiple integrals; recurrences; Pell numbers

1 Introduction

A shifted diagram of shape $\lambda = (\lambda_1, \dots, \lambda_d)$ ($\lambda_1 > \dots > \lambda_d$) is an array of $|\lambda|$ boxes, where row i containing λ_i boxes starts with its leftmost box in position (i, i) (from top to bottom). A standard shifted Young tableau of shape λ is a labeling by $\{1, 2, \dots, |\lambda|\}$ of the boxes in the shifted diagram such that each row and column is increasing (from left to right and from top to bottom respectively). Specially, a standard Young tableaux (SYT) of shifted staircase shape is $\lambda = \delta_n = (n, n - 1, \dots, 1)$. The enumeration of SYT is an important problem in enumerative combinatorics. See R. P. Stanley's monograph [10] and R. M. Adin and Y. Roichman's recent survey paper [2].

The number of SYT of shifted shape λ is given by the following product formula [8, 12]:

$$g^\lambda = \frac{|\lambda|!}{\prod_{i=1}^d \lambda_i!} \prod_{i < j} \frac{\lambda_i - \lambda_j}{\lambda_i + \lambda_j}. \quad (1)$$

A SYT of truncated shape is the SYT with some boxes removed from the NE corner, which was recently discussed by some authors [1, 7, 11]. Adin et al. in [1] derived the formulas of δ_n truncated by a square or nearly a square by the method of pivoting theory.

G. Panova independently obtained the product formulas of δ_n truncated by a box in term of Schur functions [7].

This paper considers the SYT of shifted shape $(n_1 + n_2 - 1, n_1 + n_2 - 2, \dots, n_2)$ truncated by a staircase δ_{n_1-1} , namely a SYT of truncated shifted shape with n_1 rows and n_2 boxes in each row, illustrated as follows

Let $g_{n_1, n_2}(n_1, n_2 \geq 2)$ be the number of SYT of truncated shifted shape with n_1 rows and n_2 boxes in each row. It is clear that $g_{2, n}$ is the $(n - 1)$ -th Catalan number $\frac{1}{n} \binom{2n-2}{n-1}$, $g_{n, 2} = 1$ and $g_{n, 3} = 2^{n-1}$. This kind of SYT of shifted strips with constant width has many interesting applications. Y. Baryshnikov and D. Romik. considered the situation for 90 degree clockwise rotation in [4]. J. B. Lewis conjectured that the number of alternating permutations of length $2n - 2$ avoiding the pattern 3412 is $g_{3, n}$, which summation representation was given by G. Pabova [6]. In fact, g_{n_1, n_2} is also the number of $n_1 \times n_2$ matrices containing a permutation of $[n_1 n_2]$ in increasing order rowwise, columnwise, diagonally and (downwards) antidiagonally, because the character in increasing order antidiagonally of matrix coincides with the shifted property of SYT.

Suppose $T(n, k)$ is the number of $n \times k$ matrices containing a permutation of $[nk]$ in increasing order rowwise, columnwise, diagonally and antidiagonally, R. H. Hardin gives several empirical formulas of $T(n, k)$ in case of $k \leq 7$ [9, A181196]:

Empirical Recurrence Relations (*R.H.Hardin*)

$$T(n, 4) : a_n = 6a_{n-1} - a_{n-2}. \quad (2)$$

$$T(n, 5) : a_n = 24a_{n-1} - 40a_{n-2} - 8a_{n-3}. \quad (3)$$

$$T(n, 6) : a_n = 120a_{n-1} - 1672a_{n-2} + 544a_{n-3} - 6672a_{n-4} + 256a_{n-5}. \quad (4)$$

$$T(n, 7) : a_n = 720a_{n-1} - 84448a_{n-2} + 1503360a_{n-3} - 17912224a_{n-4} - 318223104a_{n-5} \\ + 564996096a_{n-6} + 270471168a_{n-7} - 11373824a_{n-8} + 65536a_{n-9}. \quad (5)$$

In addition, Ping Sun in [11] shows that g_{n_1, n_2} is involved in the nested distribution of n_1 groups of independent order statistics with n_2 samples from uniform distribution on interval $(0, 1)$. Generally, the order statistics model of SYT in [11] implies

Proposition 1. For $n_1, n_2 \geq 2$,

$$g_{n_1, n_2} = (n_1 n_2)! \cdot J(n_1, n_2) = (n_1 n_2)! \int \cdots \int_{D(n_1, n_2)} dx_{i, j}, \quad (6)$$

where $D(n_1, n_2)$ is the following SYT-type integral domain (the variables are increasing

from left to right and from top to bottom)

$$\begin{array}{ccccccc}
0 < x_{1,1} < & x_{1,2} & < \cdots & < x_{1,n_2} \\
& \wedge & & \wedge \\
& x_{2,1} & < \cdots < & x_{2,n_2-1} & < x_{2,n_2} \\
& & \ddots & & \ddots & \ddots \\
& & & x_{n_1,1} < \cdots & \cdots & < x_{n_1,n_2} < 1.
\end{array}$$

In this paper we derive the recurrence formulas of $g_{3,n}$, $g_{n,4}$ and $g_{n,5}$ by using of the integral method of [11]. In Section 2 we evaluate the nested distribution of *three* groups of independent order statistics with n samples from uniform distribution on interval $(0, 1)$, which implies a new summation representation of $g_{3,n}$. So that a non-homogeneous linear recurrence relation of $g_{3,n}$ is given. In Section 3 we compute the corresponding multiple integrals and prove the recurrence relations (2) and (3) respectively. In particular, $g_{n,4}$ is shown to be the $(2n - 1)$ -st Pell number which implies the empirical formula (2).

2 New recurrence relation of $g_{3,n}$

There are two results of $g_{3,n}$ in the literature. Considering the enumeration of SYT of shifted shape $(n, n - 1, i)$, $0 \leq i \leq n - 2$, G. Panova gives the following summation representation.

Proposition 2. [6] For $n \geq 2$,

$$g_{3,n} = \sum_{i=0}^{n-2} \frac{(2n+i-1)!(n-i)(n-i-1)}{n! (n-1)! i! (2n-1)(n+i)(n+i-1)}. \quad (7)$$

For the number of $3 \times n$ matrices containing a permutation of $[3n]$ in increasing order rowwise, columnwise, diagonally and antidiagonally, V. Kotesovec gives the complicated order 2 recurrence relation.

Proposition 3. [9, A181197] For $n \geq 3$,

$$\begin{aligned}
(2n-1)(7n-13)n^2 \cdot g_{3,n} &= 2(182n^4 - 1185n^3 + 2722n^2 - 2625n + 900) \cdot g_{3,n-1} \\
&+ 3(2n-5)(3n-5)(3n-4)(7n-6) \cdot g_{3,n-2}, \quad g_{3,1} = 1, \quad g_{3,2} = 1.
\end{aligned} \quad (8)$$

For $0 < t_1 < t_2 < t_3 < 1$, we consider the following integral

$$J_{n-1}(t_1, t_2, t_3) = \int \cdots \int_{D(t)} dx_{i,j}, \quad n \geq 2,$$

where $D(t)$ is the following SYT-type integral domain

$$\begin{aligned}
0 < x_{i,1} < x_{i,2} < \cdots < x_{i,n-1} < t_i, \quad 1 \leq i \leq 3; \quad x_{1,2} < x_{2,1}, x_{2,n-1} < x_{3,n-2}; \\
t_1 < x_{2,n-1}, t_2 < x_{3,n-1}; \quad x_{1,j+2} < x_{2,j+1} < x_{3,j}, \quad 1 \leq j \leq n-3.
\end{aligned}$$

From Proposition 1, there is

$$g_{3,n} = (3n)! \iiint_{0 < t_1 < t_2 < t_3 < 1} J_{n-1}(t_1, t_2, t_3) dt_i, \quad n \geq 2. \quad (9)$$

Lemma 4. For $n \geq 1$, $0 < t_1 < t_2 < t_3 < 1$,

$$J_n(t_1, t_2, t_3) = \frac{t_1^n t_2^n t_3^n}{n!^3} + \frac{2}{n!(2n)!} \sum_{i=0}^{n-1} (-1)^{n-i} \binom{2n}{i} [t_1^n t_2^{2n-i} t_3^i - t_1^{2n-i} t_2^n t_3^i + t_1^{2n-i} t_2^i t_3^n]. \quad (10)$$

Proof. It is clear that

$$J_1(t_1, t_2, t_3) = t_1(t_2 - t_1)(t_3 - t_2) = t_1 t_2 t_3 - (t_1 t_2^2 - t_1^2 t_2 + t_1^2 t_3).$$

Suppose (10) is true for $n-1$, then

$$\begin{aligned} J_n(t_1, t_2, t_3) &= \iiint_{0 < x < t_1 < y < t_2 < z < t_3} J_{n-1}(x, y, z) dx dy dz \\ &= \frac{t_1^n (t_2^n - t_1^n)(t_3^n - t_2^n)}{n!^3} + \frac{2}{(n-1)!(2n-2)!} \sum_{i=0}^{n-2} (-1)^{n-1-i} \binom{2n-2}{i} \frac{1}{n(i+1)(2n-i-1)} \times \\ &\quad [t_1^n (t_2^{2n-i-1} - t_1^{2n-i-1})(t_3^{i+1} - t_2^{i+1}) - t_1^{2n-i-1} (t_2^n - t_1^n)(t_3^{i+1} - t_2^{i+1}) + t_1^{2n-i-1} (t_2^{i+1} - t_1^{i+1})(t_3^n - t_2^n)] \\ &= \frac{t_1^n t_2^n t_3^n}{n!^3} + \frac{2}{n!(2n)!} \sum_{i=0}^{n-1} (-1)^{n-i} \binom{2n}{i} [t_1^n t_2^{2n-i} t_3^i - t_1^{2n-i} t_2^n t_3^i + t_1^{2n-i} t_2^i t_3^n] + R_n(t_1, t_2, t_3), \end{aligned}$$

where

$$R_n(t_1, t_2, t_3) = (t_1^{2n} t_2^n - t_1^n t_2^{2n} - t_1^{2n} t_3^n) \left[\frac{1}{n!^3} + \frac{2}{n!(2n)!} \sum_{i=0}^{n-1} (-1)^{n-i} \binom{2n}{i} \right] = 0$$

follows from the known identity [5, 1.86]

$$\sum_{i=0}^n (-1)^i \binom{2n}{i} = (-1)^n \binom{2n-1}{n}. \quad (11)$$

The proof of lemma 4 is complete by induction. \square

It should be noted that $J_{n-1}(t_1, t_2, t_3)$ is the shifted nested conditional distribution of *three* groups of independent order statistics with n samples from uniform distribution on interval $(0, 1)$. The following result gives a non-homogeneous linear recurrence of $g_{3,n}$.

Theorem 5. For $n \geq 1$, the number $g_{3,n}$ of SYT of truncated shifted shape with 3 rows and n boxes in each row satisfies

$$g_{3,n+1} = -g_{3,n} + \frac{7n+1}{n^2(n+1)^2} \binom{2n-2}{n-1} \binom{3n}{n-1}, \quad g_{3,1} = 1. \quad (12)$$

Proof. For $n \geq 2$, combining (9) and (10) we have the summation representation

$$g_{3,n} = \frac{(3n)!}{6 \cdot n!^3} + \sum_{i=0}^{n-2} (-1)^{n-1-i} \frac{(3n-1)!(5n-3i-3)}{n! i! (2n-i-1)! (3n-i-1)!}. \quad (13)$$

Decomposing $5n - 3i - 3 = 3(3n - i - 1) - 4n$ in above summation, from (11) and Frisch's identity [5, 4.2]:

$$\sum_{i=0}^{2n-1} (-1)^i \binom{2n-1}{i} \frac{1}{n+i} = \frac{(n-1)!(2n-1)!}{(3n-1)!},$$

the summation representation (13) of $g_{3,n}$ is simplified to be

$$g_{3,n} = -\frac{4n-5}{6(2n-1)} \cdot \frac{(3n)!}{n!^3} + 4(-1)^{n-1} + (-1)^n 4n \binom{3n-1}{n} \cdot A_n, \quad (14)$$

where

$$A_n = \sum_{i=0}^n (-1)^i \binom{2n-1}{i} \frac{1}{n+i}.$$

The recurrence of A_n is not difficult to derive by using of the equality (11).

$$\begin{aligned} A_{n+1} &= \frac{1}{3n+2} \sum_{i=0}^{n+1} (-1)^i \frac{(2n+1)!}{i! (2n-i)!} \left[\frac{1}{2n+1-i} + \frac{1}{n+1+i} \right] \\ &= \frac{(-1)^{n+1} \binom{2n}{n+1}}{3n+2} + \frac{2n(2n+1)}{(3n+1)(3n+2)} \sum_{i=0}^{n+1} (-1)^i \binom{2n-1}{i} \left[\frac{1}{2n-i} + \frac{1}{n+1+i} \right] \\ &= \frac{(-1)^{n+1} (10n^3 + 8n^2 - n - 1) \binom{2n}{n+1}}{2n(n+1)(3n+1)(3n+2)} + \frac{2n(2n+1)}{(3n+1)(3n+2)} \sum_{i=0}^n (-1)^i \frac{\binom{2n-1}{i}}{n+1+i}, \end{aligned}$$

and the summation in last equality is equal to

$$\begin{aligned} &\sum_{i=0}^n (-1)^{i+1} \frac{1}{n+1+i} \left[\binom{2n-1}{i+1} - \binom{2n}{i+1} \right] \\ &= A_n + \frac{(-1)^{n+1} \left[\binom{2n-1}{n+1} - \binom{2n}{n+1} \right]}{2n+1} - \frac{1}{3n} \sum_{i=0}^n (-1)^i \frac{(2n)!}{i! (2n-1-i)!} \left[\frac{1}{n+i} + \frac{1}{2n-i} \right] \\ &= \frac{1}{3} A_n - \frac{n^2-1}{6n^2(2n+1)} (-1)^{n+1} \binom{2n}{n+1}, \end{aligned}$$

therefore the recurrence of A_n is

$$A_{n+1} = \frac{2n(2n+1)}{3(3n+1)(3n+2)} A_n + (-1)^{n+1} \frac{28n^3 + 22n^2 - n - 1}{6n(n+1)(3n+1)(3n+2)} \binom{2n}{n+1}, \quad A_1 = \frac{1}{2}.$$

So that the recurrence relation (12) of $g_{3,n}$ follows from

$$A_n = \frac{(-1)^n}{4n \binom{3n-1}{n}} g_{3,n} + \frac{1}{n \binom{3n-1}{n}} + (-1)^n \frac{4n-5}{8n(2n-1)} \binom{2n-1}{n}.$$

The proof of theorem 5 is complete. □

3 Recurrence relations of $g_{n,4}$ and $g_{n,5}$

It is well-known the Pell numbers P_n are defined by the recurrence relation [9, A000129]

$$P_n = 2P_{n-1} + P_{n-2}, \quad P_0 = 0, P_1 = 1. \quad (15)$$

The Pell numbers arise historically in the rational approximation to $\sqrt{2}$. Most recently Pell numbers were used to enumerate the numbers of certain pattern-avoiding permutations [3].

Theorem 6. *For $n \geq 1$, the number $g_{n,4}$ of SYT of truncated shifted shape with n rows and 4 boxes in each row is the $(2n - 1)$ -st Pell number P_{2n-1} , which satisfies*

$$g_{n,4} = 6g_{n-1,4} - g_{n-2,4}, \quad g_{1,4} = 1, g_{2,4} = 5. \quad (16)$$

Proof. For $1 \leq i \leq n$, write the variable t_{2i-1} corresponding to the box $(i, i + 1)$, t_{2i} corresponding to the box $(i, i + 2)$ in the SYT of shifted strip with width 4 respectively:

Proposition 1 implies that

$$g_{n,4} = (4n)! \int \int_{0 < t_{2n-1} < t_{2n} < 1} (1 - t_{2n}) J_n(t_{2n-1}, t_{2n}) dt_{2n-1} dt_{2n}, \quad n \geq 2,$$

where

$$J_n(t_{2n-1}, t_{2n}) = \int \cdots \int_{0 < t_1 < t_2 < t_3 < \cdots < t_{2n-2} < t_{2n-1}} t_1 \prod_{i=2}^n (t_{2i-1} - t_{2i-3})(t_{2i} - t_{2i-2}) dt_1 \cdots dt_{2n-2}.$$

We shall now use the method of induction to prove the following

$$J_n(t_{2n-1}, t_{2n}) = \frac{t_{2n-1}^{4n-4}}{(4n-3)!} \{ (4n-3)P_{2n-2}t_{2n} - [(4n-4)P_{2n-2} - P_{2n-3}]t_{2n-1} \}, \quad (17)$$

where P_i is the Pell number.

It is clear that

$$J_2(t_3, t_4) = \int \int_{0 < t_1 < t_2 < t_3} t_1(t_3 - t_1)(t_4 - t_2) dt_1 dt_2 = \frac{t_3^4}{5!} (10t_4 - 7t_3),$$

which agrees with (17) because $P_1 = 1, P_2 = 2$.

Furthermore, from the recurrence relation (15) of Pell numbers,

$$\begin{aligned}
J_{n+1}(t_{2n+1}, t_{2n+2}) &= \iint_{0 < t_{2n-1} < t_{2n} < t_{2n+1}} J_n(t_{2n-1}, t_{2n})(t_{2n+1} - t_{2n-1})(t_{2n+2} - t_{2n}) dt_{2n-1} dt_{2n} \\
&= \int_0^{t_{2n+1}} \frac{t_{2n}^{4n-2}}{(4n-1)!} \{ (4n-1)P_{2n-1}t_{2n+1} - [(4n-2)P_{2n-1} - P_{2n-2}]t_{2n} \} (t_{2n+2} - t_{2n}) dt_{2n} \\
&= \frac{t_{2n+1}^{4n}}{(4n+1)!} [(4n+1)P_{2n}t_{2n+2} - (4nP_{2n} - P_{2n-1})t_{2n+1}],
\end{aligned}$$

which shows (17) is true. Therefore,

$$\begin{aligned}
g_{n,4} &= (4n)! \iint_{0 < t_{2n-1} < t_{2n} < 1} (1 - t_{2n}) J_n(t_{2n-1}, t_{2n}) dt_{2n-1} dt_{2n} \\
&= \frac{(4n)!}{(4n-3)!} \int_0^1 \left[P_{2n-2} - \frac{(4n-4)P_{2n-2} - P_{2n-3}}{4n-2} \right] t_{2n}^{4n-2} (1 - t_{2n}) dt_{2n} \\
&= 4n(4n-1) \int_0^1 P_{2n-1} t_{2n}^{4n-2} (1 - t_{2n}) dt_{2n} = P_{2n-1}.
\end{aligned}$$

It is clear (16) follows from the recurrence relation of Pell number. \square

Theorem 7. For $n \geq 4$, the numbers $g_{n,5}$ of SYT of truncated shifted shape with n rows and 5 boxes in each row satisfy the following recurrence relation

$$g_{n,5} = 24g_{n-1,5} - 40g_{n-2,5} - 8g_{n-3,5}, \quad g_{1,5} = 1, g_{2,5} = 14, g_{3,5} = 290. \quad (18)$$

Proof. We shall derive the recurrence of $g_{n,5}$ from the relations of certain integrals. For convenient, write the variables $0 < x_i < y_i < z_i < s_i < t_i < 1$ corresponding to the five boxes in row i ($1 \leq i \leq n$) in the SYT of shifted strip with width 5 respectively.

$$\begin{array}{ccccccc}
& \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
& & & & & & \\
\boxed{x_{n-1}} & \boxed{y_{n-1}} & \boxed{z_{n-1}} & \boxed{s_{n-1}} & \boxed{t_{n-1}} & & \\
& \boxed{x_n} & \boxed{y_n} & \boxed{z_n} & \boxed{s_n} & \boxed{t_n} &
\end{array}$$

From Proposition 1, we have

$$g_{n,5} = (5n)! \int \cdots \int_{D(n,5)} dx_i dy_i dz_i ds_i dt_i = (5n)! \cdot J_n(5).$$

Consider the following integral

$$D_n(x_n, y_n, z_n, s_n) = \int \cdots \int_{\substack{D_{n-1,5}, y_{n-1} < x_n, \\ z_{n-1} < y_n, s_{n-1} < z_n, t_{n-1} < s_n}} dx_1 y_1 z_1 s_1 t_1 \cdots dx_{n-1} y_{n-1} z_{n-1} s_{n-1} t_{n-1},$$

$J_n(5)$ can be written to be

$$\begin{aligned}
J_n(5) &= \int \cdots \int_{\substack{0 < x_{n-1} < y_{n-1} < z_{n-1} < s_{n-1} < t_{n-1} < s_n, \\ s_{n-1} < z_n, z_{n-1} < y_n < z_n < s_n < t_n < 1}} (y_n - y_{n-1}) D_{n-1}(x_{n-1}, \cdots, s_{n-1}) dx_{n-1} \cdots t_{n-1} dy_n \cdots t_n \\
&= \int \cdots \int_{\substack{0 < z_{n-1} < s_{n-1} < t_{n-1} < s_n, \\ s_{n-1} < z_n, z_{n-1} < y_n < z_n < s_n < t_n < 1}} (A_n y_n - B_n) dz_{n-1} s_{n-1} t_{n-1} dy_n z_n s_n t_n,
\end{aligned} \tag{19}$$

where A_n and B_n are linear combinations of terms involved in z_{n-1} and s_{n-1} with coefficients $C_i(n)$, that is

$$\begin{aligned}
A_n &= \iint_{0 < x_{n-1} < y_{n-1} < z_{n-1}} D_{n-1}(x_{n-1}, \cdots, s_{n-1}) dx_{n-1} dy_{n-1} \\
&= C_1(n) \frac{z_{n-1}^{5n-9}}{(5n-9)!} s_{n-1} - C_2(n) \frac{z_{n-1}^{5n-8}}{(5n-8)!}, \\
B_n &= \iint_{0 < x_{n-1} < y_{n-1} < z_{n-1}} y_{n-1} D_{n-1}(x_{n-1}, \cdots, s_{n-1}) dx_{n-1} dy_{n-1} \\
&= C_3(n) \frac{z_{n-1}^{5n-8}}{(5n-8)!} s_{n-1} - C_4(n) \frac{z_{n-1}^{5n-7}}{(5n-7)!}.
\end{aligned}$$

Notice that

$$\begin{aligned}
A_{n+1} &= \iint_{0 < x_n < y_n < z_n} D_n(x_n, \cdots, s_n) dx_n dy_n \\
&= \int \cdots \int_{\substack{0 < z_{n-1} < s_{n-1} < t_{n-1} < s_n, \\ s_{n-1} < z_n, z_{n-1} < y_n < z_n < s_n}} (A_n y_n - B_n) dz_{n-1} s_{n-1} t_{n-1} y_n,
\end{aligned} \tag{20}$$

then

$$\begin{aligned}
A_{n+1} &= [10(n-1)(5n-7)C_1(n) - (10n-11)C_2(n) - (10n-11)C_3(n) + 2C_4(n)] \times \\
&\quad \frac{z_n^{5n-4}}{(5n-4)!} s_n - [(5n-4)(5n-7)(10n-11)C_1(n) - 2(5n-4)(5n-6)C_2(n) \\
&\quad - 50(n-1)^2 C_3(n) + (10n-9)C_4(n)] \frac{z_n^{5n-3}}{(5n-3)!}.
\end{aligned}$$

By the similar arguments,

$$\begin{aligned}
B_{n+1} &= \iint_{0 < x_n < y_n < z_n} y_n D_n(x_n, \dots, s_n) dx_n dy_n \\
&= \int \cdots \int_{\substack{0 < z_{n-1} < s_{n-1} < t_{n-1} < s_n, \\ s_{n-1} < z_n, z_{n-1} < y_n < z_n < s_n}} (A_n y_n^2 - B_n y_n) dz_{n-1} s_{n-1} t_{n-1} y_n \\
&= [(5n-4)(5n-7)(10n-11)C_1(n) - 50(n-1)^2 C_2(n) - 2(5n-4)(5n-6)C_3(n) \\
&\quad + (10n-9)C_4(n)] \frac{z_n^{5n-3}}{(5n-3)!} s_n - (5n-3)[2(5n-4)(5n-6)(5n-7)C_1(n) \\
&\quad - (5n-6)(10n-9)C_2(n) - (5n-6)(10n-9)C_3(n) + 10(n-1)C_4(n)] \frac{z_n^{5n-2}}{(5n-2)!}.
\end{aligned}$$

Therefore, For $n \geq 2$, the recurrence relations of $C_i(n)$ ($1 \leq i \leq 4$) are

$$\begin{aligned}
C_1(n+1) &= 10(n-1)(5n-7)C_1(n) - (10n-11)C_2(n) - (10n-11)C_3(n) + 2C_4(n), \\
C_2(n+1) &= (5n-4)(5n-7)(10n-11)C_1(n) - 2(5n-4)(5n-6)C_2(n) \\
&\quad - 50(n-1)^2 C_3(n) + (10n-9)C_4(n), \\
C_3(n+1) &= (5n-4)(5n-7)(10n-11)C_1(n) - 50(n-1)^2 C_2(n) \\
&\quad - 2(5n-4)(5n-6)C_3(n) + (10n-9)C_4(n), \\
C_4(n+1) &= 2(5n-3)(5n-4)(5n-6)(5n-7)C_1(n) - (5n-3)(5n-6)(10n-9)C_2(n) \\
&\quad - (5n-3)(5n-6)(10n-9)C_3(n) + 10(n-1)(5n-3)C_4(n),
\end{aligned}$$

with the initial values

$$\begin{aligned}
C_1(2) &= 0, \quad C_2(2) = -1, \quad C_3(2) = 0, \quad C_4(2) = -2, \\
C_1(3) &= 5, \quad C_2(3) = 26, \quad C_3(3) = 28, \quad C_4(3) = 168.
\end{aligned}$$

On the other hand, combining (19) and (20), we have

$$\begin{aligned}
J_n(5) &= \iiint_{0 < z_n < s_n < t_n < 1} A_{n+1} dz_n s_n t_n \\
&= \iiint_{0 < z_n < s_n < t_n < 1} [C_1(n+1) \frac{z_n^{5n-4}}{(5n-4)!} s_n - C_2(n+1) \frac{z_n^{5n-3}}{(5n-3)!}] dz_n s_n t_n \\
&= \frac{(5n-2)C_1(n+1) - C_2(n+1)}{(5n)!},
\end{aligned}$$

then,

$$g_{n,5} = (5n-2)C_1(n+1) - C_2(n+1), \quad (21)$$

and

$$g_{n,5} = (5n - 7)(25n - 24)C_1(n) - (25n - 26)C_2(n) - (25n - 28)C_3(n) + 5C_4(n), \quad (22)$$

which follows from (21) and the recurrences of $C_i(n)$.

Furthermore, by using of the recurrence relations of $C_i(n)$ again, (22) implies

$$\begin{aligned} g_{n+1,5} &= (5n - 2)(25n + 1)C_1(n + 1) - (25n - 1)C_2(n + 1) \\ &\quad - (25n - 3)C_3(n + 1) + 5C_4(n + 1) \\ &= (5n - 7)(550n - 524)C_1(n) - (550n - 590)C_2(n) \\ &\quad - (550n - 594)C_3(n) + 110C_4(n). \end{aligned} \quad (23)$$

So that from (21)-(23) we have

$$\begin{aligned} g_{n+1,5} &= 22g_{n,5} + 4(5n - 7)C_1(n) + 18C_2(n) - 22C_3(n) \\ &= 22g_{n,5} + 4g_{n-1,5} + 22[C_2(n) - C_3(n)]. \end{aligned}$$

Finally, the recurrence relation of $C_i(n)$ shows

$$C_2(n + 1) - C_3(n + 1) = 2[C_2(n) - C_3(n)], \quad n \geq 2$$

which implies

$$g_{n+1,5} - 22g_{n,5} - 4g_{n-1,5} = 2(g_{n,5} - 22g_{n-1,5} - 4g_{n-2,5}).$$

The initial values $g_{1,5} = 1$, $g_{2,5} = 14$ and $g_{3,5} = 290$ are obvious, then the proof of theorem 7 is complete. □
