Abstract

Let $\kappa_{max}(\Sigma)$ denote the maximum value for the connectivity of any graph which embeds in the topological surface Σ. The connectivity interval for Σ is the set of integers in the interval $[1, \kappa_{max}(\Sigma)]$. Given an integer i in $[1, \kappa_{max}(\Sigma)]$ it is a trivial problem to demonstrate that there is a graph G_i with connectivity i which also embeds in Σ. We will say that one can *saturate* the connectivity interval in this case.

Note that no restrictions have been placed on the embeddings in the above problem, however. What if we demand that the embeddings in question be 2-*cell* or even that they be *genus* embeddings?

The problem of saturating the connectivity interval for 2-cell embeddings will be solved completely in the present work. In connection with the apparently much harder saturation question for genus embeddings, it will be shown that one can always saturate the subinterval $[1, \lfloor 0.7\kappa_{max}(\Sigma) \rfloor]$.

1. Introduction

In his 1973 paper, Cook [C1] studied the relation between the connectivity of a graph and the surfaces into which it can be embedded. He proved that the following result holds for all surfaces except the plane:

$$\kappa(G) \leq \left\lfloor \frac{5 + \sqrt{49 - 24\chi}}{2} \right\rfloor,$$

where $\kappa(G)$ denotes the vertex connectivity of graph G and χ is the Euler characteristic of any surface in which G embeds. Moreover, Cook showed that these bounds are attained by complete graphs in all cases except the Klein bottle.

In [PZ1] we explored in more detail relations between the connectivity of embedded graphs and the surfaces in which they are embedded. Let $\kappa_{max}(\Sigma)$ denote the maximum connectivity among all graphs which embed in Σ and let $\kappa_{gen}(\Sigma)$ be the maximum connectivity among all graphs which *genus* embed in Σ. It was shown that, somewhat surprisingly, κ_{gen} is not a monotone non-decreasing function of the genus. Also for some surfaces, κ_{gen} is strictly less than κ_{max}. In fact it was proved that such so-called *Class B* surfaces are not only infinite in number, but that they must occur infinitely often periodically as the genus parameter increases to infinity. It was also shown that in the case when the complete graph which attains Cook's maximum connectivity bound actually genus embeds in the surface, that with a finite number of exceptions, it is the unique graph attaining this bound.

Let us begin the present work by considering a very easy problem. If G_{max} is a graph which embeds in a surface Σ and $\kappa(G_{max}) = \kappa_{max}$ for that surface, then by removing edges all incident with a common vertex one by one, it is trivial to construct a sequence of graphs $G_r = G_{max}, G_{r-1}, \ldots, G_2, G_1$ such that $\kappa(G_i) = i$ and each G_i embeds in the surface. In this case, we say that we can *saturate* the connectivity interval $[1, \kappa_{max}]$.

But note that nothing was said about the nature of the embeddings along the way. In particular, it was not demanded that they be 2-*cell* or that they be *genus* embeddings. In the present paper, the focus will be on two questions:

Question 1: Given a surface Σ and an integer i, does there exist a graph G with $\kappa(G) = i$ such that G 2-*cell* embeds in Σ (i.e., each face is homeomorphic to an open disk)?

Question 2: Let Σ and i be as in Question 1. Does there exist a graph G with $\kappa(G) = i$ such that G *genus* embeds in Σ?

With the aid of theorems by Duke [D1] and Stahl [S1], we will answer Question 1 completely. The solution is not difficult. Regarding the second question, it will be shown that for $i \in [1, \lfloor 0.7\kappa_{max} \rfloor]$, Question 2 has a positive answer.

In fact the second question appears to be quite difficult. For one thing, all embeddings sought must be genus embeddings and the genus problem for graphs is known to be NP-complete. (See [T1].) Thus one needs to construct special genus embeddings with the required connectivity the genera of which are easy to determine. Also for

certain values of i in Question 2, an affirmative answer to the question turns out to imply an answer to an unsolved problem of long standing. Let $O(m)$ denote the generalized octahedron graph which is obtained from the complete graph K_m by deleting a maximum matching. When m is even and $m/2 \equiv 0, 1(\mod 3)$, the orientable genus of $O(m)$ is known. (See [AG1] and [JR1].) Determination of the orientable genus of $(O(m))$ remains open for the remaining values of m.

Let i in Question 2 be the connectivity of $O(m)$ ($= m - 2$). Then by Theorems 5.1 and 5.2 of [PZ1], this special case of Question 2 actually implies the answer to the problem of determining the orientable genus of $O(m)$ for certain of the remaining values of m. This will be explained in more detail in the final section of the present paper.

Most of the proofs to follow involve constructions of graphs and embeddings such that (1) the embeddings are genus embeddings and (2) the graphs have the correct connectivity.

2. Saturation of the Connectivity Interval for 2-cell Embeddings

In this section, we proceed to answer Question 1 of the Introduction. As usual, $\gamma(G)$ (respectively, $\overline{\gamma}(G)$) will denote the orientable (respectively, non-orientable) genus of graph G. An embedding of a graph G in a surface S is said to be a **2-cell** embedding if every face is homeomorphic to an open disk. The **maximum orientable** (respectively **maximum non-orientable) genus** $\gamma_M(G)$ (respectively $\overline{\gamma}_M(G)$) of graph G is the largest genus of any orientable surface S (respectively, non-orientable surface N) in which G has a 2-cell embedding.

The following results due to Duke [D1] in the orientable case and to Stahl [S1] in the non-orientable case guarantee that there is a 2-cell embedding of G in all surfaces with genera values between and including those of the minimum and maximum surfaces.

Theorem 2.1. If $\gamma(G) \leq \gamma \leq \gamma_M(G)$ (or if $\overline{\gamma}(G) \leq \overline{\gamma} \leq \overline{\gamma}_M(G)$), then there is a 2-cell embedding of G in the orientable surface of genus γ (respectively, in the non-orientable surface of genus $\overline{\gamma}$).
∎

Let G be a connected graph and let T be an arbitrary spanning tree of G. The **deficiency** $\xi(G,T)$ of spanning tree T is the number of components of $G - E(T)$ which have an odd number of edges. The **deficiency** $\xi(G)$ of graph G is the minimum of $\xi(G,T)$ over all spanning trees T. Finally, let $\beta(G)$, called the **Betti number** or **cyclomatic number** of a connected graph G be defined by $\beta(G) = |E(G)| - |V(G)| + 1$.

Xuong [X1] and Edmonds [E2] have characterized the maximum orientable and non-orientable genus of a graph G in terms of its Betti number and its deficiency.

Theorem 2.2. If $\gamma_M(G)(\overline{\gamma}_M(G)), \xi(G)$ and $\beta(G)$ represent the maximum orientable (non-orientable) genus of a connected graph G, the deficiency of G and the Betti number of G respectively, then $\gamma_M(G) = (1/2)(\beta(G) - \xi(G))$ and $\overline{\gamma}_M(G) = \beta(G)$.
∎

We make use of Theorem 2.2 in the next result which states that one can saturate the interval of connectivity $[1, \kappa_{max}]$ with 2-cell embeddings for any surface orientable or non-orientable. Thus Question 1 in Section 1 has a complete affirmative answer.

Theorem 2.3. If Σ is any surface, orientable or non-orientable, then for any integer i in the interval $[1, \kappa_{max}(\Sigma)]$, there is a graph G with connectivity i which 2-cell embeds in Σ.

Proof: First consider the orientable case. Let S_g be any orientable surface, let i be any integer in the interval $[1, \kappa_{max}(S_g)]$, and let K_m be the largest complete graph which embeds in S_g. Note that we do not assume that this embedding is necessarily 2-cell. If $g = 0$ then the surface is the sphere, $\kappa_{max}(sphere) = 5$, and the theorem is trivial. If $g = 1$ then the surface is the torus, and $\kappa_{max}(torus) = 6$. Negami [N1] has shown that there are 6-connected triangulations of the torus (which therefore are 2-cell embeddings). We shall refer to these graphs as "Negami graphs". It is an easy matter to modify one of his graphs to obtain graphs with $\kappa = 1, \ldots, 5$ which also 2-cell embed on the torus.

So henceforth we will assume that $g \geq 2$ and $m \geq 8$. Suppose i is an integer in the connectivity subinterval $[1, m-1]$. Let G_i be a graph obtained from K_m by deleting $m - i - 1$ edges all incident with a common vertex v. Then $\kappa(G_i) = m - (m - i - 1) - 1 = i$.

Clearly $\gamma(G_i) \leq \gamma(K_m) \leq g < \gamma(K_{m+1})$. We now show that $\gamma_M(G_i) \geq \gamma(K_{m+1})$. By Theorem 2.2, $\gamma_M(G_i) = (1/2)(\beta(G_i) - \xi(G_i))$. Moreover, $\beta(G_i) = 1 - m + [m(m-1)/2 - (m - i - 1)] = m(m-1)/2 - 2m + i + 2$.

It is easy to construct a spanning tree T of G_i such that $G_i - E(T)$ consists of only one component. (Such a tree is called a **splitting tree**; see White [W1].) Therefore $\xi(G_i) = 0$ if $G - E(T)$ has an even number of edges and $\xi(G_i) = 1$ if $G - E(T)$ has an odd number of edges. Thus $\gamma_M(G_i) \geq (1/2)(\beta(G_i) - 1) = (1/2)(m(m-1)/2 - 2m + i + 2) = m(m-1)/4 - m + (1/2)i + 1 > m(m-1)/4 - m + 1$. So

$$\gamma_M(G_i) - \gamma(K_{m+1}) > \frac{m(m-1)}{4} - m + 1 - \left\lceil \frac{(m-2)(m-3)}{12} \right\rceil$$

$$\geq \frac{m(m-1)}{4} - m + 1 - \frac{(m-2)(m-3)}{12} - 1$$

$$= \frac{m^2 - 5m - 3}{6} > \frac{(m-6)(m+1)}{6} > 0,$$

since $m \geq 8$.

Thus $\gamma_M(G_i) \geq \gamma(K_{m+1}) \geq g$ and hence $\gamma(G_i) \leq \gamma(K_m) < \gamma(K_{m+1}) \leq \gamma_M(G_i)$. Thus by Theorem 2.1, G_i has a 2-cell embedding for every genus in the interval $[\gamma(G_i), \gamma_M(G_i)]$ which includes the interval $[\gamma(K_m), \gamma(K_{m+1})]$ which in turn includes the genus g. This completes the proof in the orientable case.

The proof for the non-orientable case parallels that for the orientable case.

∎

3. Constructions IA, IB and IC — the Orientable Case

Starting in this Section, we will address the more difficult Question 2. We will construct some *simple* graphs together with genus embeddings thereof and for each of these constructions, we will derive the genus and the connectivity. Let $\gamma(s, k)$ denote the orientable genus of K_m where $m = 12s + k, s \geq 1$ and $0 \leq k \leq 11$. For each value of $k = 0, \ldots, 11$ and for each $s \geq 1$ we define the function $l_k(s)$ by $l_k(s) = 2[\gamma(s, k+1) - \gamma(s, k)]$ for $k \neq 2, 5$, and $l_k(s) = 2[\gamma(s, k+1) - \gamma(s, k)] + 2$ for $k = 2, 5$, Then by the Ringel-Youngs Theorem [R1], $\gamma(s, k) = 12s^2 + 2sk - 7s + \lceil (k^2 - 7k + 12)/12 \rceil$ and it follows that

$$l_k(s) = \begin{cases} 4s, & \text{if } k = 0, 1, 2, 3, 6, \\ 4s + 2, & \text{if } k = 4, 5, 7, 8, 9, 10, 11 \end{cases}$$

It is known [R1] that when $k = 2, 5$, the graph $K_m - K_2$ can be genus embedded into the surface $S_{\gamma(s,k)-1}$. Then for each of the twelve possible values of k, i.e., $k = 0, 1, \ldots, 11$, let Ψ denote a genus embedding of K_m into surface $S_{\gamma(s,k)}$ when $k \neq 2, 5$ and a genus embedding of $K_m - K_2$ into surface $S_{\gamma(s,k)-1}$, when $k = 2$ or 5.

Then let Ψ' be a second copy of K_m (respectively, $K_m - K_2$ when $k = 2, 5$) into a second copy of the surface $S_{\gamma(s,k)}$ (respectively, $S_{\gamma(s,k)-1}$ when $k = 2, 5$) in identically the same way. Now choose a value for l, $1 \leq l \leq l_k(s)$. We proceed to choose l faces of Ψ and l faces of Ψ' in a certain way and then to connect the two surfaces via l "cylinders" or "tubes" joining the interiors of the faces chosen in Ψ to the interiors of the faces chosen in Ψ'.

If $k = 2, 5$, let v_0 be any vertex of $K_m - K_2$ which is not an endvertex of the missing edge. (If $k = 2$ or 5, it is known that Ψ is a triangulation [R1] [RY1] [J1].) In this case let $v_1, \ldots, v_{m-1}$ denote the other vertices of Ψ in clockwise order about the vertex v_0. Then for each $i = 1, \ldots, m - 2$, let f_i be the face incident with v_0 which contains edges $v_0 v_i$ and $v_0 v_{i+1}$ in its boundary.

Fix a value for λ, $1 \leq \lambda \leq l \leq l_k(s)$. We select λ of the faces f_i which are consecutive about v_0 and then every second face until we have chosen a total of l faces in Ψ. In particular, we define our "chosen" faces F_i by:

$$F_i = \begin{cases} f_i, & 1 \leq i \leq \lambda, \\ f_{2i-\lambda}, & \lambda + 1 \leq i \leq l. \end{cases}$$

Now we turn our attention to Ψ'. In Ψ', denote the vertex corresponding to v_i in Ψ by v_i' for $i = 0, \ldots, m - 1$. In Ψ', starting from the face F_1', select every other face incident with v_0' and call these faces $F_1', \ldots, F_l'$ (in any order). Name the two vertices on the boundary of F_i' that are adjacent to v_0' by a_i' and b_i', respectively.

For the cases when $k = 1, 6, 9, 10$, we shall proceed slightly differently. We know that the embedding is not a triangulation, so select a non-triangular face F of Ψ as F_1, and the corresponding face in Ψ' as F_1'. Since face F_1 is not a triangle, we can choose four vertices v_0, v_1, v, v_2 on the boundary of F_1 such that edges $v_0 v_1$ and $v_0 v_2$ are adjacent boundary edges of F_1. We may name v_1 and v_2 such that as one traverses the boundary of F_1, one encounters the vertices v_1, v and v_2 in clockwise order. In these

cases when choosing the faces F_i' in Ψ' we should not choose any face with edge $v_0'v'$ on its boundary.

It is important to have this non-triangular face so that we may add an extra edge on the first tube in our construction. This additional edge will suffice to attain the bound in Lemma 3.1 below.

For the remaining cases when $k = 0, 3, 4, 7, 8$ and 11, choose vertices $v_0, v_1, \ldots, v_{m-1}$ as we did for the cases $k = 2$ and 5.

For each $i, 1 \leq i \leq l$, insert a tube T_i joining the interiors of faces F_i and F_i'. We now add edges to form a new graph on $2m$ vertices as follows. For $1 \leq i \leq \lambda$, add edges $v_0a_i', v_0b_i', v_iv_0', v_ia_i', v_ib_i', v_{i+1}a_i'$ all on tube T_i. Also when $k = 1, 6, 9, 10$ add the "extra" edge v_0v' on tube T_1. When $\lambda + 1 \leq i \leq l$, add edges $v_0a_i', v_0b_i', v_{2i-\lambda}v_0', v_{2i-\lambda}a_i', v_{2i-\lambda}b_i'$ and $v_{2i-\lambda+1}a_i'$ all on tube T_i. (See Figure 3.1.)

We will call the embedded graph on $2m$ vertices constructed above $H_{IA}(s, k, l, \lambda)$. It is important to note that all edges added across the l tubes in the above construction are distinct; i.e., graph $H_{IA}(s, k, l, \lambda)$ has no multiple edges. This is because all faces chosen in Ψ' only have v_0' on their common boundary, and hence all a_i''s and b_i''s are distinct. The parameter λ which is the number of consecutive faces chosen in Ψ determines the connectivity of the resulting graph.

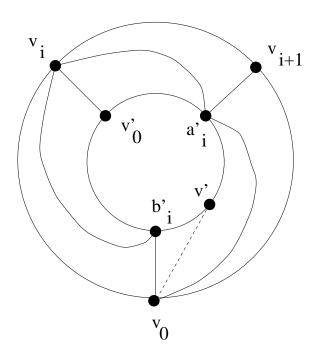

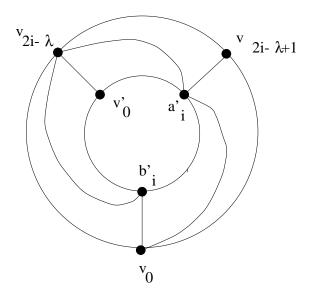

Figure 3.1(a)

Figure 3.1(b)

We proceed to determine the genus and the connectivity of the graph $H_{IA}(s, k, l, \lambda)$. We will make use of the following corollary of Euler's formula (see [W1, pg. 62 and pg. 179]).

Lemma 3.1. For all simple graphs G with p vertices and q edges,

$$\gamma(G) \geq \frac{q}{6} - \frac{p}{2} + 1,$$

and

$$\overline{\gamma}(G) \geq \frac{q}{3} - p + 2.$$

Furthermore, equality holds in the above inequalities if and only if there is a triangular embedding of G in its surface of minimum genus.

∎

Now we compute the genus and connectivity of $H_{IA}(s, k, l, \lambda)$.

Theorem 3.2.
   (i) The embedding of $H_{IA}(s, k, l, \lambda)$ constructed above is a genus embedding, and

$$\gamma(H_{IA}(s, k, l, \lambda)) = \begin{cases} 2\gamma(s, k) + l - 1, & \text{for } k \neq 2, 5, \\ 2\gamma(s, k) + l - 3, & \text{for } k = 2, 5. \end{cases}$$

   (ii) For all $s \geq 1$, $\kappa(H_{IA}(s, k, l, \lambda)) = 2l - \lambda + 2$.

Proof: First suppose that $k \neq 2$ or 5. Denote $H_{IA}(s, k, l, \lambda)$ by H. Then $p_H = 2m = 2(12s + k)$ and $q_H = (12s + k)(12s + k - 1) + 6l + \epsilon_k$, where

$$\epsilon_k = \begin{cases} 0 & \text{if } k \neq 1, 6, 9, 10, \\ 1 & \text{if } k = 1, 6, 9, 10. \end{cases}$$

Then by Lemma 3.1,

$$\gamma(H) \geq \left\lceil \frac{q}{6} - \frac{p}{2} + 1 \right\rceil$$

$$= \left\lceil \frac{1}{6}((12s + k)(12s + k - 1) + 6l + \epsilon_k) - (12s + k) + 1 \right\rceil$$

$$= 24s^2 + 4sk - 14s + l + \left\lceil \frac{k^2 - 7k + 6 + \epsilon_k}{6} \right\rceil.$$

Let us denote the right side of the final equation above by A.

On the other hand, it is known (cf. [R1]) that $\gamma(K_{12s+k}) = 12s^2 + 2sk - 7s + \lceil (k^2 - 7k + 12)/12 \rceil$. Denote the right side of this equality by B. Then in each of the ten cases when $k \neq 2, 5$, it is easy to check that $A = 2B + l - 1$. But we know that the constructed surface is obtained by joining l tubes between two surfaces each having genus B. Therefore the genus of the constructed surface is $2B + l - 1$.

Now suppose $k = 2$ or 5. Then $p_H = 2(12s + k)$ as before, but now $q_H = 2((12s + k)(12s + k - 1)/2 - 1) + 6l$, so

$$\gamma(H) \geq \left\lceil \frac{q}{6} - \frac{p}{2} + 1 \right\rceil$$

$$= 24s^2 + 4sk - 14s + l + \left\lceil \frac{k^2 - 7k + 4}{6} \right\rceil.$$

If we denote the right side of the last equality by A' then again it is easy to show that $A' = 2B + l - 3$ when $k = 2$ and $k = 5$. In these two cases the constructed surfaces are obtained by joining l tubes between two surfaces each having genus $B - 1$, and therefore the genus of the constructed surface is $2B + l - 3$. This proves (i).

Now we consider the connectivity of graph $H_{IA}(s, k, l, \lambda)$.

Since $1 \leq \lambda \leq l \leq l_k(s)$, it is easy to check that, for all $m = 12s + k$ and $s \geq 1$.

$$2l - \lambda + 2 \leq \begin{cases} m - 3, & \text{for } k \neq 2, 5 \text{ and} \\ m - 4, & \text{for } k = 2, 5. \end{cases}$$

It now follows that given two vertices u and w both in Ψ, or both in Ψ', since when $k \neq 2, 5$, K_m is $(m - 1)$-connected and when $n = 2, 5$, $K_m - K_2$ is $(m - 2)$-connected, there must be more than $2l - \lambda + 2$ vertex-disjoint $u - w$ paths in $H_{IA}(s, k, l, \lambda)$). So we need only treat the remaining case, namely, when u is a vertex in Ψ and w is a vertex in Ψ'.

Since

$$M = \{v_i b_i' | 1 \le i \le \lambda\} \cup \{v_{2i-\lambda} b_i' | \lambda + 1 \le i \le l\} \cup \{v_{2i-\lambda+1} a_i' | \lambda \le i \le l\} \cup \{v_0 a_1'\}.$$

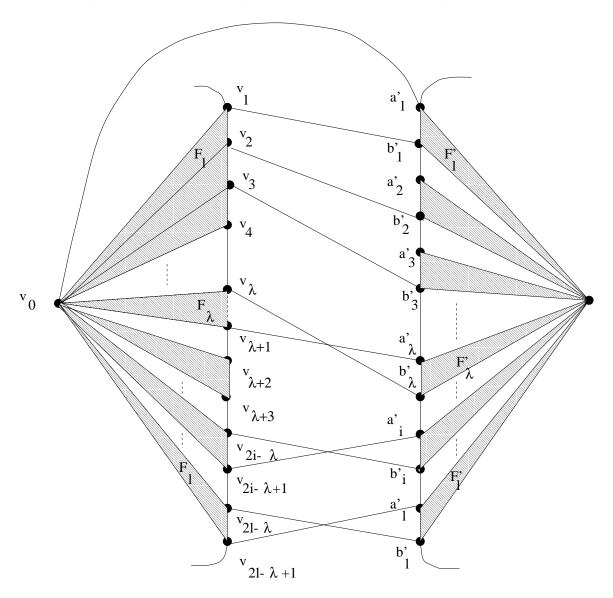

Figure 3.2

(See Figure 3.2.) is a matching of size $2l - \lambda + 2$ from vertices in Ψ to vertices in Ψ', we have $2l - \lambda + 2$ vertex-disjoint paths, using these matching edges to join $u \in \Psi$ and $v \in \Psi'$. Therefore $\kappa(H_{IA}(s, k, l, \lambda)) \ge 2l - \lambda + 2$. Since the set of all vertices of matching M lying in Ψ is a vertex cut, we have $\kappa(H_{IA}(s, k, l, \lambda)) \le 2l - \lambda + 2$. Thus $\kappa(H_{IA}(s, k, l, \lambda)) = 2l - \lambda + 2$, and the proof of the Theorem is complete. ∎

Note that $\kappa(H_{IA}(s,k,l,1)) = 2l+1$ and for all λ, $2 \le \lambda \le l$, $\kappa(H_{IA}(s,k,l,\lambda)) \le 2l+1$. For saturation purposes, the value of $\kappa(H_{IA}(s,k,l,1))$ is not quite high enough, so we extend our Construction IA to include, for all values of k, a graph $H_{IB}(s,k,l)$ having $\kappa = 2l+2$ and for $k = 1,6,8,9,10$ and 11, a graph $H_{IC}(s,k,l)$ having $\kappa = 2l+3$.

To build graphs $H_{IB}(s,k,l)$ and $H_{IC}(s,k,l)$, we modify the Construction IA in the case $\lambda = 1$ as follows. Let Ψ be constructed just as before and let the faces $F_1 = f_1, F_2 = f_3, \ldots, F_{l-1} = f_{2l-3}$ which meet only at vertex v_0 be as before. We proceed to modify the choice of face F_l as follows. For graph $H_{IB}(s,k,l)$, let F_l be the face formed by taking the two consecutive faces f_{2l-1} and f_{2l} and deleting their common boundary edge $v_0 v_{2l}$. (It is an easy calculation to show that since $s \ge 1$, there are enough faces at v_0 to make the above selection in such a way that faces f_{2l} and f_1 have no common boundary edge.)

We proceed to choose faces $F_1', \ldots, F_l'$ in exactly the same way relative to embedding Ψ' as $F_1, \ldots, F_l$ were chosen relative to embedding Ψ.

Thus faces F_l and F_l' will have at least four distinct vertices in their facial walks.

Now, as before, we insert tubes T_i joining the interiors of F_i and F_i', for $i = 1, \ldots, l$. For each tube T_i, $i = 1, \ldots, l-1$ we add edges across T_i exactly as we did in Construction IA.

Recall that face F_l is at least a quadrilateral and the four vertices v_0, v_{2l-1}, v_{2l} and v_{2l+1} appear in clockwise order about the boundary of F_l. Similarly in the embedding Ψ', the vertices $v_0', v_{2l-1}', v_{2l}', v_{2l+1}'$ lie in counterclockwise order along the face boundary of F_l'.

Across tube T_l we insert the eight edges $v_0 v_{2l}', v_0 v_{2l+1}', v_{2l-1} v_{2l+1}',$ $v_{2l-1} v_0', v_{2l} v_0', v_{2l} v_{2l-1}', v_{2l+1} v_{2l-1}', v_{2l+1} v_{2l}'$. (See Figure 3.3.)

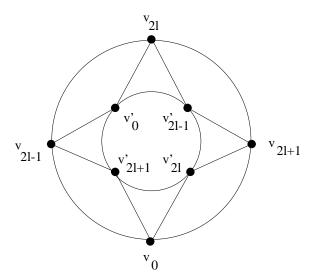

Figure 3.3

To construct graph $H_{IC}(s,k,l)$, for $k = 1,6,8,9,10,11$, proceed just as in the

construction of graph $H_{IB}(s,k,l)$ up through the selection of faces F_1 through F_{l-1}.

But this time let F_l be the face formed by considering the three consecutive faces f_{2l-1}, f_{2l} and f_{2l+1} and deleting the edges v_0v_{2l} and v_0v_{2l+1}. (Again it is easy to show that for each value of k, $k \in \{1,6,8,9,10,11\}$, faces f_{2l+1} and f_1 have no common boundary edge.) Thus this time, Ψ and Ψ' are both embeddings of K_m with two adjacent edges removed. Thus the five vertices $v_0, v_{2l-1}, v_{2l}, v_{2l+1}, v_{2l+2}$ appear in clockwise order about the boundary of F_l.

Faces $F_1', \ldots, F_l'$ are chosen similarly, except that $v_0', v_{2l-1}', v_{2l}', v_{2l+1}'$ and v_{2l+2}' lie in *counter*-clockwise order along the face boundary of F_l'.

Thus faces F_l and F_l' will have at least five distinct vertices in their facial walks.

Add tubes $T_1, \ldots, T_l$ and six edges across each of $T_1, \ldots, T_{l-1}$ exactly as before. Next, across tube T_l we insert the ten edges $v_0v_{2l+1}', v_0v_{2l+2}', v_{2l-1}v_{2l+2}', v_{2l-1}v_0', v_{2l}v_0',$ $v_{2l}v_{2l-1}', v_{2l+1}v_{2l-1}', v_{2l+1}v_{2l}', v_{2l+2}v_{2l}', v_{2l+2}v_{2l+1}'$.

Theorem 3.3.
(i) The above embeddings of $H_{IB}(s,k,l)$ and $H_{IC}(s,k,l)$ are genus embeddings, and

$$\gamma(H_{IB}(s,k,l)) = \begin{cases} 2\gamma(s,k) + l - 1 & \text{for } k \neq 2,5, \\ 2\gamma(s,k) + l - 3 & \text{for } k = 2,5, \text{ and} \end{cases}$$
$$\gamma(H_{IC}(s,k,l)) = 2\gamma(s,k) + l - 1 \text{ for } k = 1,6,8,9,10 \text{ and } 11 \text{ and}$$

(ii) $\kappa(H_{IB}(s,k,l)) = 2l + 2$ and $\kappa(H_{IC}(s,k,l)) = 2l + 3$.

Proof: The proof proceeds just as in the proof of Theorem 3.2. For Part (i), the only difference is that here for $H_{IB}(s,k,l)$ we have deleted one edge from each of Ψ and Ψ', but have added two additional edges across tube T_1. Thus the total edge counts remain the same as in Theorem 3.2 in all cases. Similarly, for $H_{IC}(s,k,l)$, we have deleted two edges from each of Ψ and Ψ', but have added four additional edges across T_1 and again the total edge counts remain the same as in Theorem 3.2 in all cases.

For Part (ii), the only difference is that, in $H_{IB}(s,k,l)$ and $H_{IC}(s,k,l)$, the size of the matching from Ψ to Ψ' are increased by 1 and 2, respectively. This increases the connectivity of the graphs by 1 and 2, respectively.

∎

4. Construction II — the Orientable Case

In this section we will construct graphs and orientable embeddings thereof such that the connectivities of these graphs will cover a higher range of values than that covered by the graphs and embeddings constructed in Section 3.

As before, let $m = 12s + k$ and assume $s \geq 1$ and $0 \leq k \leq 11$. Let us once again begin by genus embedding graph K_m into orientable surface $S_{\gamma(s,k)}$ when $k \neq 2, 5$ and genus embedding graph $K_m - K_2$ into $S_{\gamma(s,k)-1}$ when $k = 2$ or 5. Call this embedding Ψ_0. Now take another identical embedding of the same graph in the same surface and call it Ψ_0'.

Again this time we will first modify the underlying graphs of the two embeddings, and then proceed to link the two embeddings of the modified graphs with a collection of l tubes. Once again we then insert new edges across these tubes so as to form one larger graph embedded in the composite surface.

Let us start with $k = 2$ or 5. Since Ψ_0 is an embedding of $K_m - K_2$, let v_0 denote any vertex not an endvertex of the missing edge. Remembering that Ψ_0 is a triangulation in these cases, let us label the vertices about vertex v_0 as $v_1, \ldots, v_{m-1}$ in clockwise order such that v_1 is also not an endvertex of the missing edge.

Label the vertices in Ψ_0' as $v_0', \ldots, v_{m-1}'$ in exactly the same way as the vertices were labeled in Ψ_0. Therefore the labels appear in the clockwise order around v_0 and v_0', as indicated in Figure 4.1. This ordering is important to avoid multiple edges in the constructions.

Now suppose $k = 0, 3, 4$ or 7. Since Ψ_0 is a triangulation in these cases, choose any vertex and label it v_0. Then label the other $m - 1$ vertices as $v_1, \ldots, v_{m-1}$ clockwise about v_0. Again do exactly the same labeling in Ψ_0'.

For the remaining values of k, namely, $k = 1, 6, 8, 9, 10$ and 11, since Ψ_0 is not a triangulation, there must exist a face of embedding Ψ_0 which is of size at least 4. Choose four vertices on the boundary of this face which are consecutive in a clockwise direction about this face and call them v_2, v_0, v_1 and v respectively. It is important to have this non-triangular face. For each of these cases, the addition of two extra edges on one of the connecting tubes suffices to attain the genus bound in Lemma 3.1.

Now in all twelve cases (for each of the twelve values of k) delete vertex v_0 and denote the new face formed by F_0. Once again repeat the above labeling and subsequent vertex deletion in exactly the same way in Ψ_0' and label with F_0' that face which corresponds to F_0. Call the resulting embeddings Ψ and Ψ' respectively. We now have a face with all other vertices in $\Psi(\Psi')$ on its boundary. This is a major difference from the constructions in Section 3. By inserting a tube between these two big faces and adding edges on this tube, the resulting graph has higher connectivity than that obtained using Construction I. When inserting edges across the various tubes, we need to take particular care to avoid multiple edges.

Insert a tube (or cylinder) T_0 with one end in the interior of face F_0 and the other end in the interior of face F_0'.

Now suppose $l_k(s)$ is still defined as in Section 3 and suppose $1 \leq l \leq l_k(s)$. Here l will denote the *total* number of connecting tubes we will insert between Ψ and Ψ' and

hence tube T_0 will be counted by l. We proceed to locate and insert the remaining $l-1$ tubes.

Let us choose $l-1$ faces $F_1, \ldots, F_{l-1}$ clockwise about vertex v_1 such that the boundary of F_i contains the adjacent edges $v_1 a_i$ and $v_1 b_i$, vertices v_1, a_i and b_i are labeled in clockwise order about face F_i, and such that

(1) no two of the F_i have a common boundary edge,

(2) if $k = 1, 6, 8, 9, 10, 11$, then for all $1 \le i \le l-1$, $\{a_i, b_i\} \cap \{v_2, v, v_{m-1}\} = \emptyset$, and

(3) if $k = 0, 2, 3, 4, 5, 7$, then for all $1 \le i \le l-1$, $\{a_i, b_i\} \cap \{v_2, v_{m-1}\} = \emptyset$.

(It is easy to check that for all twelve values of k, such a selection of $l-1$ faces F_i is possible, since $s \ge 1$.) Note that these a_i's and b_i's are neighbor vertices of v_1, and they are labeled as v_i's on the face boundary of F_0.

Again, make precisely the same selection of faces in Ψ'. Then, for each $i = 1, \ldots, l-1$, insert a tube T_i joining the interiors of faces F_i and F_i'. Then for each i, $1 \le i \le l-1$, across tube T_i add the six edges $v_1 a_i', v_1 b_i', a_i a_i', a_i v_1', b_i v_1', b_i b_i'$.

We now proceed to add edges across tube T_0 as follows. Suppose α is an integer variable such that $3 \le \alpha \le m-2$. Consider the edge set $\{v_1 v_1', v_1 v_2', v_2 v_1', v_2 v_{m-1}', v_2 v_{m-2}'\} \cup \{v_i v_{m-i+1}' | 3 \le i \le \alpha-1\} \cup \{v_i v_{m-i}' | 3 \le i \le \alpha-1\} \cup \{v_\alpha v_j' | 2 \le j \le m-\alpha+1\} \cup \{v_i v_2' | \alpha \le i \le m-1\}$. In the cases when $k = 1, 6, 8, 9, 10, 11$ we add to this set the two additional edges $v_1 v'$ and $v v_1'$.

Finally, if $\alpha < \lfloor (m+1)/2 \rfloor$ and if v_α is one of the a_i's or b_i's, then we do not add edge $v_\alpha v_\alpha'$ across tube T_0 because it already exists on one of the tubes $T_1, \ldots, T_{l-1}$. Similarly, if $\alpha \ge \lfloor (m+1)/2 \rfloor$ and if $v_{\lfloor (m+1)/2 \rfloor}$ is one of the a_i's or one of the b_i's, then we do not add edge $v_{\lfloor (m+1)/2 \rfloor} v_{\lfloor (m+1)/2 \rfloor}'$ across tube T_0 as it already exists on one of $T_1, \ldots, T_{l-1}$. (See Figure 4.1.)

Call the resulting graph on $2m-2$ vertices $H_{II}(s, k, l, \alpha)$.

Lemma 4.1. Each graph $H_{II}(s, k, l, \alpha)$ is simple.

Proof: On tube T_0, the edges incident with v_1 and v_1' are $v_1 v_1', v_1 v_2', v_2 v_1'$ and (possibly) $v v_1'$ and $v_1 v'$. On the other hand, on tube T_i the edges incident with v_1 and v_1' are $v_1 a_i', v_1 b_i', a_i b_i', a_i v_1', b_i v_1'$. But $\{a_i, b_i\} \cap \{v_2, v, v_{m-1}\} = \emptyset$ and and $\{a_i', b_i'\} \cap \{v_2', v', v_{m-1}'\} = \emptyset$, so none of these edges is multiple.

The remaining edges on T_i are of the form $a_i a_i'$ or $b_i b_i'$. But on T_0 we have constructed no such edges, because of the reversed order of v_i's and v_i''s.

∎

Let us now compute the genus of $H_{II}(s, k, l, \alpha)$.
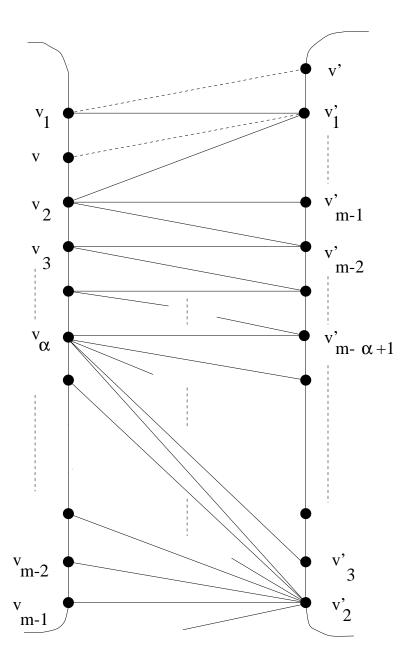

Figure 4.1

Theorem 4.2. The embedding of $H_{II}(s, k, l, \alpha)$ constructed above is a genus embedding and

$$\gamma(H_{II}(s, k, l, \alpha)) = \begin{cases} 2\gamma(s, k) + l - 3, & \text{if } k = 2, 5, \\ 2\gamma(s, k) + l - 1, & \text{if } k \neq 2, 5. \end{cases}$$

Proof: For each $k = 0, \dots, 11$, we have embedded $H_{II}(s, k, l, \alpha)$ in a surface with the required genus. Now noting that $q \geq 2[m(m-1)/2 - (m-1) - 1] + 6(l-1) + 2(m-1)$, when $k = 2, 5$; $q \geq 2[(m-1)(m-2)/2 + 2(m-1) + 6(l-1) - 1$, when $k = 0, 3, 4$ or 7; and $q \geq 2(m-1)(m-2)/2 + 2(m-1) + 2 + 6(l-1) - 1$, when $k = 1, 6, 8, 9, 10$ or 11; and that $p = 2(m-1)$ in all twelve cases, by Lemma 3.1 and an easy counting exercise we obtain

$$\gamma(H_{II}(s, k, l, \alpha)) \geq \begin{cases} 2\gamma(s, k) + l - 3, & \text{if } k = 2, 5, \\ 2\gamma(s, k) + l - 1, & \text{if } k \neq 2, 5, \end{cases}$$

and the theorem is proved.

∎

Now consider the connectivity of graph $H_{II}(s, k, l, \alpha)$. Since we have two independent parameters α and l, in general it is impossible to determine when v_α is one of the a_i's or one of the b_i's. Moreover, the edges on the tubes T_i, $i \geq 1$, may affect the connectivity of the graphs. So it is not easy to find the *exact* value of κ. However, as we shall see below, the exact value will not be required.

To this end, it will be convenient to introduce some new terminology. Let any matching which matches vertices of Ψ with vertices of Ψ' be called a **left-right matching** (or *LR*-**matching**). Let $\nu_{LR}(H_{II}(s, k, l, \alpha))$ denote the size of any largest *LR*-matching in $H_{II}(s, k, l, \alpha)$.

Theorem 4.3.

$$\kappa(H_{II}(s, k, l, \alpha)) \geq \begin{cases} \nu_{LR}(H(s, k, l, \alpha)) & \text{if } k \neq 2, 5 \\ \min\{\nu_{LR}(H(s, k, l, \alpha)), m - 2\} & \text{if } k = 2, 5. \end{cases}$$

Proof: Denote $H_{II}(s, k, l, \alpha)$ by H. Suppose u and w are two vertices of H. We want to consider the maximum number of vertex-disjoint paths between u and w.

First suppose $k \neq 2, 5$. If u and w are both in Ψ, then there exist $m - 2$ disjoint paths joining them in Ψ since Ψ is an embedding of K_{m-1}. It is easy to construct one additional path joining u and w by using vertices in Ψ'. Similarly, for u and w both in Ψ', it is easy to construct $m - 1$ disjoint paths joining them.

So it will suffice to consider the case with u is in Ψ and w is in Ψ'.

Let M_α be a maximum *LR*-matching and suppose that the endvertices of M_α in Ψ are $x_1, \dots, x_j$, $j = \nu_{LR}$. Now $j \leq m - 1$, so since Ψ is an embedding of K_{m-1}, there exist $j \leq m - 1$ disjoint paths from u to each of the vertices $x_1, \dots, x_j$. These paths are all single edges, unless $u \in \{x_1, \dots, x_j\}$ and in that case one of the paths is of length 0. Similarly there exist j disjoint paths from w to the endvertices of M_α in Ψ'. Thus there are $j = \nu_{LR}$ disjoint u-v paths in H. Hence $\kappa(H) \geq \nu_{LR}$ as claimed.

Now suppose $k = 2$ or 5. Then, if $\nu_{LR} \leq m - 2$, proceeding exactly as in the case for $k \neq 2, 5$, it may be shown that there are at least ν_{LR} disjoint paths joining u and w. Finally, if $\nu_{LR} > m - 2$, that is, if $\nu_{LR} = m - 1$, then $\alpha = m - 2$ and once again it is

easy to find $m - 2$ disjoint paths joining every two vertices u and w in H. The theorem follows.

∎

If we set $\alpha = m - 2$ in the above theorem, we obtain the next result.

Corollary 4.4.

$$\kappa(H_{II}(s, k, l, m - 2)) \begin{cases} = m - 1 & \text{when } k \neq 2, 5 \text{ and} \\ \geq m - 2 & \text{when } k = 2, 5. \end{cases}$$

Proof: Equality follows in the case $k \neq 2, 5$ since deg $(v'_{m-1}) = m - 1$.

∎

The next result shows that if one increases parameter α by 1, the corresponding connectivity of $H_{II}(s, k, l, \alpha)$ changes by at most 1.

Lemma 4.5. If $3 \leq \alpha \leq m - 3$, then

$$\kappa(H_{II}(s, k, l, \alpha)) - 1 \leq \kappa(H_{II}(s, k, l, \alpha + 1)) \leq \kappa(H_{II}(s, k, l, \alpha)) + 1.$$

Proof: Denote $H_{II}(s, k, l, \alpha)$ by $H_{II}(\alpha)$. Note first that $H_{II}(\alpha) - v_\alpha$ is a spanning subgraph of $H_{II}(\alpha + 1) - v_\alpha$, so $\kappa(H_{II}(\alpha)) - 1 \leq \kappa(H_{II}(\alpha) - v_\alpha) \leq \kappa(H_{II}(\alpha + 1) - v_\alpha) \leq \kappa(H_{II}(\alpha + 1))$ and the first inequality is proved.

Next note that $H_{II}(\alpha + 1) - v_{\alpha+1}$ is a spanning subgraph of $H_{II}(\alpha) - v_{\alpha+1}$ and so $\kappa(H_{II}(\alpha + 1)) - 1 \leq \kappa(H_{II}(\alpha + 1) - v_{\alpha+1}) \leq \kappa(H_{II}(\alpha) - v_{\alpha+1}$ and so $\kappa(H_{II}(\alpha + 1)) \leq \kappa(H_{II}(\alpha) - v_{\alpha+1}) + 1 \leq \kappa(H_{II}(\alpha)) + 1$ and the second inequality is verified.

∎

Now the proof of the following theorem is immediate.

Theorem 4.6. Suppose $a = \kappa(H_{II}(s, k, l, 3))$ and

$$b = \begin{cases} m - 1, & \text{if } k \neq 2, 5 \text{ and} \\ m - 2, & \text{if } k = 2, 5. \end{cases}$$

Then for any $\kappa_0 \in [a, b]$ there is an $\alpha \in [3, m - 3]$ such that $\kappa(H_{II}(s, k, l, \alpha)) = \kappa_0$.

∎

Theorem 4.6 tells us the value of b in the interval of connectivities $[a, b]$ which we can saturate. The next result gives us a useful upper bound on the other endpoint a.

Theorem 4.7.

$$\kappa(H_{II}(s, k, l, 3)) \leq \begin{cases} 2l + 3 & \text{when } k = 1, 6, 8, 9, 10 \text{ or } 11 \text{ and} \\ 2l + 2 & \text{when } k = 0, 2, 3, 4, 5, 7. \end{cases}$$

Proof: The set

$$S_0 = \begin{cases} \{v_1, v_2, v_3, v_2', v\}, & \text{when } k = 1, 6, 8, 9, 10, 11, \text{ and} \\ \{v_1, v_2, v_3, v_2'\}, & \text{when } k = 0, 2, 3, 4, 5, 7, \end{cases}$$

covers all edges crossing tube T_0 and hence the set $S = S_0 \cup \{a_1, b_1, \ldots, a_{l-1}, b_{l-1}\}$ covers all edges crossing any of the total of l tubes. So set S is a cutset separating vertex v_{m-1}, say, from the remaining vertices of Ψ' and has the size claimed in the statement of the theorem.

∎

Now we turn our attention to the high end of the connectivity interval $[a, b]$ discussed above. By Theorem 4.6 we know that for each l we can saturate $[2l + 3, m - 1]$, when $k = 1, 6, 8, 9, 10, 11$, over $[2l + 2, m - 1]$ when $k = 0, 3, 4, 7$, and over $[2l + 2, m - 2]$ when $k = 2, 5$. For saturation reasons we want to construct graphs with genus $= \gamma(H_{II}(s, k, l, \alpha))$ and built from $H_{II}(s, k, l, \alpha)$ by modifying the arrangement of edges on tube T_0 so that the resulting graphs have connectivities $m - 1$ when $k = 2, 5$ and m when $k \neq 2, 5$.

If $k = 0, 3, 4$ or 7, begin just as in the case of $H_{II}(s, k, l, m - 2)$ as far as selecting faces and placing tubes is concerned. Suppose that $k = 1, 6, 7, 8, 9, 10$ or 11. In locating tubes $T_1, \ldots, T_{l-1}$, we modify our previous choices for the a_i's and b_i's so that $\{a_i, b_i\} \cap \{v_2, v_{m-1}, v\} = \emptyset$.

Suppose, then, that $k = 2$ or 5. Recall that we began the construction in this case by embedding a copy of $K_m - K_2$ and then deleted vertex v_0 which was not a vertex of the missing edge. Denote this missing edge by xy. Let us now choose our $l - 1$ pairs $\{a_i, b_i\}$ so that $\{a_i, b_i\} \cap \{v_2, v_{m-1}, x\} = \emptyset$.

For $k = 0, 3, 4, 7$ and for $k = 2, 5$, modify the graph $H_{II}(s, k, l, m - 2)$ by replacing edges $v_1 v_2'$ and $v_2 v_1'$ with edges $v_1 v_{m-1}'$ and $v_{m-1} v_1'$. When $k = 1, 6, 8, 9, 10, 11$, modify $H_{II}(s, k, l, m - 2)$ by replacing edges $v_1 v_2', v_1 v', vv_1'$ and $v_2 v_1'$ with edges $v_1 v_{m-1}', vv_{m-1}'$, $v_{m-1} v'$ and $v_{m-1} v_1'$. In each case, denote the graph obtained by $H_I(k, l, m)$.

Theorem 4.8.

$$\kappa(H_I(k, l, m)) = \begin{cases} m, & \text{if } k \neq 2, 5 \text{ and} \\ m - 1, & \text{if } k = 2, 5. \end{cases}$$

Proof: Among the edges across tube T_0 call $v_1 v_1', v_2 v_{m-1}', v_3 v_{m-2}', \ldots, v_{m-1} v_2'$, the **horizontal** matching, and call $v_1 v_{m-1}', v_2 v_{m-2}', v_3 v_{m-3}', \ldots, v_{m-2} v_2', v_{m-1} v_1'$ the **slanted** matching. (It is important to realize that the edge $v_{\lfloor (m+1)/2 \rfloor} v_{\lfloor (m+1)/2 \rfloor}'$ will be present, whether it is drawn on one of the tubes $T_1, \ldots, T_{l-1}$ or on the tube T_0.)

First, suppose $k = 0, 3, 4$ or 7.

Let u and w be two vertices of $H_I(k, l, m)$. If both vertices lie in Ψ, then it is easy to find m vertex-disjoint paths joining them, where two of these paths use vertices of Ψ'. By symmetry, if both lie in Ψ', there are m vertex-disjoint paths joining them as well.

Now suppose u lies in Ψ and w lies in Ψ'; say, without loss of generality that $u = v_i$ and $w = v'_j$.

(i) First suppose $j \leq m - i$. There are three subcases.

(i-1) Suppose $j = m - i$, that is, suppose edge $v_i v'_j$ is an edge of the slanted matching.

Then there are $m - 3$ $u - w$ paths of length 3, using the $m - 3$ horizontal matching edges incident with $v_1, \ldots, v_{i-1}, v_{i+2}, \ldots, v_{m-1}$. To these we add the three additional $u - w$ paths $v_i v'_{j+1} v'_j, v_i v'_j, v_i v_{i+1} v'_j$ to obtain a total of m vertex-disjoint $u - w$ paths.

(i-2) Suppose $j = m - i - 1$. There are $m - 4$ $u - w$ paths of length 3, using the $m - 4$ horizontal matching edges incident with $v_1, \ldots, v_{i-1}, v_{i+3}, \ldots, v_{m-1}$. To these we add the four additional $u - w$ paths $v_i v'_{j+2} v'_j, v_i v'_{j+1} v'_j, v_i v_{i+1} v'_j$ and $v_i v_{i+2} v'_j$, to obtain our m vertex-disjoint $u - w$ paths.

(i-3) Suppose $j \leq m - i - 2$; say, $j = m - t$, for some $t \geq i + 2$. In this case, there are $m - 4$ $u - w$ paths of length 3, using the horizontal matching edges incident with vertices $v_1, \ldots, v_{i-1}, v_{t+2}, v_{t+3}, \ldots, v_{m-1}$ together with the slanted matching edges incident with vertices $v_{i+1}, \ldots, v_{t-1}$. To these paths we add the additional four paths of length 2: $v_i v'_{m-i+1} v'_j, v_i v'_{m-i} v'_j, v_i v'_t v'_j$ and $v_i v_{t+1} v'_j$.

(ii) Next, suppose $j = m - i + 1$.

In this case we use the $m - 3$ slanted matching edges incident with the $m - 3$ vertices $v_1, v_2, \ldots, v_{i-2}, v_{i+1}, \ldots, v_{m-1}$, together with the three paths $v_i v_{i-1} v'_j, v_i v'_j$ and $v_i v'_{j+1} v'_j$ to get m vertex-disjoint $u - w$ paths.

(iii) Finally, suppose $j > m - i + 1$.

This is the same as Case (i), if one performs the same cyclic relabeling on both sides.

On the other hand, however, $\deg_{H_I(k,l,m)}(v_{m-1}) = m$, so $\kappa(H_I(k,l,m)) = m$ as claimed.

It then follows that $\kappa(H_I(k,l,m)) = m$ in the cases $k = 1, 6, 8, 9, 10$ and 11, for observe that the "extra vertex" v is just one of the vertices $v_1, \ldots, v_{m-1}$ appearing at a different place on the facial walk of the face produced by the deletion of vertex v_0.

Next, suppose $k = 2$ or 5. We need to show that $\kappa(H_I(k,l,m)) = m - 1$. Notice that, when $k = 2$ or 5, as opposed to the cases when $k \neq 2$ or 5, there is only one edge missing in each of Ψ and Ψ', and these two missing edges are on different sides of the $LR-$matching on tube T_0. Since $\kappa(H_I(k,l,m)) = m$ for $k \neq 2, 5$, by a similar argument, it is not hard to check that $\kappa(H_I(k,l,m)) = m - 1$ for $k = 2, 5$.
∎

Theorem 4.9. The embedding of $H_I(k,l,m)$ constructed above is a genus embedding and

$$\gamma(H_I(k,l,m)) = \begin{cases} 2\gamma(s,k) + l - 3, & \text{if } k = 2, 5, \\ 2\gamma(s,k) + l - 1, & \text{if } k \neq 2, 5. \end{cases}$$

Proof: The proof is very similar to that of Theorem 4.2.
∎

5. The Interval of Saturation–the Orientable Case

Before presenting the main theorem of this section, it is necessary to have the following results for surfaces of small orientable genus.

Lemma 5.1. Let g be an integer such that $0 \leq g \leq 9$. Then for every integer $i \in [1, \kappa_{max}(S_g)]$, there is a graph G with $g = \gamma(G)$ and $\kappa(G) = i$.

For $g = 10, 11$, and every integer $i \in [1, (\sqrt{2}/2)\kappa_{max}(S_g)]$, there is a graph G with $g = \gamma(G)$ and $\kappa(G) = i$.

Proof: When $g = 0$, it is well known that there are planar graphs having vertex connectivity 5,4,3,2 and 1.

Secondly, we claim that it follows from the results of Negami [N1] that for every surface with orientable genus ≥ 1 (or non-orientable genus ≥ 2), there are graphs of that genus which have connectivity 6, have a vertex of degree 6, and which triangulate the surface. To see this in the orientable case, one need only start Negami's construction with a 6-regular 6-connected graph which triangulates the torus and has sufficiently many vertices so that not all vertices of the beginning graph are subsequently affected by Negami's construction. Similarly, if one begins with a 6-connected 6-regular triangulation of the Klein bottle which has sufficiently many vertices, at least one vertex of degree 6 will remain unmodified by the Negami construction.

Moreover, since the Negami graphs are all triangulations, one may remove up to five edges incident with a vertex of degree 6 without lowering the genus. Therefore we have the following proposition.

Proposition: Starting with a 6-connected triangulation of genus $\gamma \geq 1$ (or genus $\overline{\gamma} \geq 2$) which has a vertex of degree 6, there are graphs with connectivity 5,4,3,2 and 1 all of which have genus γ (or $\overline{\gamma}$).

First consider the (orientable) genera 2 and 3. Since $\gamma(K_8) = 2, \kappa(K_8) = 7 = \kappa(S_2), \gamma(K_9) = \gamma(K_9 - K_2) = 3, \kappa(K_9) = 8 = \kappa_{max}(S_3), \kappa(K_9 - K_2) = 7$, the lemma is true for $\gamma = 2$ and 3.

Next consider the case when $\gamma = 4$. Recall that $\gamma(K_{10}) = 4$. Again by edge counting it is easily seen that the genus of each of $K_{10} - K_2$ and $K_{10} - 2K_2$ (where $2K_2$ denotes two edges having a common vertex) is also 4. So there are genus 4 graphs having connectivities $1, \ldots, 9$, where $\kappa_{gen}(S_4) = \kappa_{max}(S_4) = 9$.

Similarly, there are graphs with $\kappa = 1, \ldots, 10$ having $\gamma = 5$ and $\kappa_{gen}(S_5) = \kappa_{max}(S_5)$
$= 10$ as well as graphs with $\kappa = 1, \ldots, 11$ having $\gamma = 6$ where $\kappa_{gen}(S_6) = \kappa_{max}(S_6) = 11$.

For S_7 our approach is somewhat different. Embed K_9 and K_{10}, choose a vertex v_0 from K_9 and a vertex v_0' from the K_{10}, delete each, and insert cylinder T_0, just as in Construction II (see Section 4). (We do not add any additional tubes this time.) Insert the following edges: $v_i v_i'$ and $v_i v_{i+1}'$ for $i = 1, \ldots, 8$; $v_1 v'$ and $v_8 v_1'$. It is then easy to check that the resulting graph is 9-connected and a simple edge count, together with Lemma 3.1, shows that the genus of this graph is 7 as desired. Modify this embedding

by inserting different edges on tube T_0 can produce graphs with $\kappa = 7$ and 8 with genus 7.

Consider next S_8. The **octahedron** $K_{7(2)}$, obtained from the complete graph K_{14} by deleting a perfect matching has connectivity 12 and by [JR1,AG1], genus 8. If an arbitrary vertex is selected and up to five edges incident with this vertex are removed, an edge count shows that each of the resulting graphs still has genus 8. In this way graphs having connectivity $7, \ldots, 11$ are created. Thus the full connectivty interva for the surface S_8 can be saturated.

The graph $K_{14} - K_2$ triangulates the surface S_9 by [RY1] and [J1] and has connectivity 12. Again by a simple edge count it is easy to show that up to five edges can be deleted from some fixed vertex of this graph without lowering the genus of the resulting graph. So we can get genus 9 graphs having connectivity $1, \ldots, 12$ and thus can saturate the full connectivity interval for the surface S_9.

For surface S_{10} we return to a modification of Construction II. Embed two copies of K_{11}, delete a vertex from each and construct the tube T_0 just as in Construction II. Across T_0 construct edges $v_i v_i'$ and $v_i v_{i+1}'$ for $i = 1, \ldots, 9$ as well as edges $v_{10} v_{10}'$ and $v_{10} v_1'$. The resulting graph has $\kappa = 11$ and an edge count verifies that the genus is indeed 10. A modification of the edge construction across T_0 similar to that done above for the genus 7 case yields genus 10 graphs having connectivity $1, \ldots, 11$ and since $(\sqrt{2}/2)\kappa_{max}(S_{10}) = 9$, we are done. Surface S_{11} is handled in much the same way as S_{10}. Embed K_{11} in S_5, K_{12} in S_6, delete a vertex from each and add tube T_0 as well as edges across T_0 as before. As before, graphs having connectivity $1, \ldots, 11$ can be constructed all of which have genus 11. But $(\sqrt{2}/2)\kappa_{max}(S_{11}) = 9$ and again we are done. ∎

We now need to construct genus embeddings whose connectivity cover the lower range of values in connectivity intervals. In doing so, we will make use of a graph operation which will be called *splitting*. Suppose graph G is n-connected, where $n \geq 2$, and suppose $v \in V(G)$ with deg $v = n$. Partition the neighborhood $N_G(v)$ into $A \cup B$ where $A \cap B = \emptyset$ and $|A| \geq 1$ and $|B| \geq 1$. Form a new graph G' from G by deleting vertex v, inserting two new vertices v_1 and v_2 such that v_1 is adjacent to each vertex in A, vertex v_2 is adjacent to each vertex in B and v_1 is adjacent to v_2. Suppose $|A| = a$ and $|B| = b$. We then say that graph G' is obtained from graph G by an (a, b)-**split at vertex** v.

Lemma 5.2. Let G be a graph with $\kappa(G) \geq 2$ and let v be a vertex in G. Let G' be a graph obtained from graph G by an (a, b)-split at vertex v and suppose $r = \min \{1 + a, 1 + b\} \leq \kappa(G)$. Then $\kappa(G') = r$.

Proof. Note that $|N_{G'}(v_i)| \geq r$, for $i = 1, 2$.

Now let S' be a minimum vertex cutset in G' and suppose $|S'| < r$.

If $\{v_1, v_2\} \cap S' = \emptyset$, then clearly S' is a cutset in G since v_1 and v_2 lie in the same component of $G' - S'$. So $\kappa(G) \leq |S'| < r \leq \kappa(G)$, a contradiction.

If $\{v_1, v_2\} \subseteq S'$, then $S = S' - v_1 - v_2 + v$ is a vertex cut in G and hence $\kappa(G) = |S| = |S'| - 1 < r - 1 \leq \kappa(G) - 1$, again a contradiction.

So we may assume that $|\{v_1, v_2\} \cap S'| = 1$. Without loss of generality, assume $v_1 \in S'$ and $v_2 \notin S'$. Let C be the component of $G' - S'$ containing vertex v_2. If $|C| \geq 2$, then $S = S' - v_1 + v$ is a cutset in G and $\kappa(G) \leq |S| = |S'| < r \leq \kappa(G)$ and once more we have a contradiction. So $|C| = 1$; that is, $V(C) = \{v_2\}$. But then $N_{G'}(v_2) \subseteq S'$ and hence $r \leq |N_{G'}(v_2)| \leq |S'| < r$, and yet again we have a contradiction.

So $|S'| \geq r$ and hence $\kappa(G') = |S'| \geq r$. But G' has a vertex of degree r, namely either vertex v_1 or v_2, and so $\kappa(G') = r$ as claimed.

■

We now are prepared to assemble Lemma 5.2 and the results of the previous two sections in order to prove the following theorem.

Theorem 5.3. Suppose g is any non-negative integer. For each orientable surface S_g define the quantity m_g by $m_0 = 5$, $m_1 = 6$ and for $g \geq 2$ by

$$m_g = \left\lfloor \frac{5 + \sqrt{1 + 48\lfloor \frac{g}{2} \rfloor}}{2} \right\rfloor + 1.$$

Write $m_g = 12s + k$, where $0 \leq k \leq 11$. Then for all integers i in the interval $[1, m_g]$ when $k \neq 2, 5$ (respectively, in the interval $[1, m_g - 1]$ when $k = 2$ or 5), there exists a graph G with $\gamma(G) = g$ and $\kappa(G) = i$.

Proof: If $g \leq 11$, the result is immediate by Lemma 5.1.
So assume $g \geq 12$ and hence $s \geq 1$.
Cook [C1] has shown that if $g/2 > 0$,

$$\kappa_{max}(S_{\lfloor \frac{g}{2} \rfloor}) = \left\lfloor \frac{5 + \sqrt{1 + 48\lfloor \frac{g}{2} \rfloor}}{2} \right\rfloor = m_g - 1,$$

and this bound is realized by the complete graph $K_m = K_{m_g}$. Let $m_g = m = 12s + k \geq 12$ and define l by

$$l = \begin{cases} g - 2\gamma(s, k) + 1, & \text{if } k \neq 2, 5, \\ g - 2\gamma(s, k) + 3, & \text{if } k = 2, 5. \end{cases}$$

1. Suppose $k = 0, 3, 4$ or 7.
By performing splitting (see Lemma 5.2) on graph $H_I(k, l, m)$, we can saturate the interval $[1, 6s + \lceil (k + 1)/2 \rceil]$, by Theorems 3.2 and 3.3 we can saturate $[l + 2, 2l + 2]$, by Theorems 4.7 and 4.6 we can saturate $[2l + 3, m - 1]$, and by Theorem 4.8, we can extend the last interval to $[2l + 3, m]$.

2. Suppose $k = 1, 6, 8, 9, 10$ or 11.
By performing splitting on graph $H_I(k, l, m)$, again we can saturate the interval $[1, 6s + \lceil (k + 1)/2 \rceil]$, by Theorem 3.2 we can saturate interval $[l + 2, 2l + 1]$ and by Theorem 3.3 we can extend this to $[l + 2, 2l + 3]$. Again by Theorems 4.7 and 4.6 we can saturate $[2l + 3, m - 1]$ and by Theorem 4.8 we can extend this to $[2l + 3, m]$.

3. Finally suppose $k = 2$ or 5.

In this case, performing splitting on graph $H_I(k, l, m)$ yields saturation of $[1, 6s + \lfloor (k+1)/2 \rfloor]$, Theorem 3.2 yields saturation of $[l+2, 2l+1]$ and Theorem 3.3 allows us to extend this to $[l+2, 2l+2]$. Then Theorems 4.7 and 4.6 allow saturation of $[2l+2, m-2]$ and Theorem 4.8 allows us to extend this to $[2l+2, m-1]$.

It is routine to check that for $k \neq 2, 5$, we have $6s + \lceil (k+1)/2 \rceil \geq l+1$ and when $k = 2, 5$, we have $6s + \lfloor (k+1)/2 \rfloor \geq l+1$. But then we have shown that when $k \neq 2, 5$, we can saturate $[1, m]$ and when $k = 2$ or 5, we can saturate $[1, m-1]$.

Finally note that by Theorems 3.2, 3.3, 4.2 and 4.9, the genus of each graph constructed for this saturation is g. This completes the proof of the theorem.

∎

Theorem 5.4. For every integer $g \geq 0$, let m_g be defined as in Theorem 5.3. Then when $0 \leq g \leq 9$, for every integer i in $[1, \kappa_{max}(S_g)]$, and when $g \geq 10$, for every integer i in $[1, \lfloor (\sqrt{2}/2) \kappa_{max}(S_g) \rfloor]$, when $m_g \not\equiv 2, 5(\bmod 12)$ and for every integer i in $[1, \lfloor 0.7 \kappa_{max}(S_g) \rfloor]$ when $m_g \equiv 2, 5(\bmod 12)$, there exists a graph G with connectivity i which genus embeds in surface S_g.

Proof: The result is immediate by Lemma 5.1 when $g \leq 11$, so suppose $g \geq 12$. First suppose that $m_g \not\equiv 2, 5(\bmod 12)$.

Let us consider the ratio

$$\frac{m_g}{\kappa_{max}} = \frac{\left\lfloor \frac{5+\sqrt{1+48\lfloor \frac{g}{2} \rfloor}}{2} \right\rfloor + 1}{\left\lfloor \frac{5+\sqrt{1+48g}}{2} \right\rfloor}.$$

We want to show that $m_g / \kappa_{max} \geq \sqrt{2}/2$.

Case 1. Assume g is odd. Let $g = 2t + 1$. Then

$$\frac{m_g}{\kappa_{max}} = \frac{\left\lfloor \frac{5+\sqrt{1+48t}}{2} \right\rfloor + 1}{\left\lfloor \frac{5+\sqrt{49+96t}}{2} \right\rfloor} = \frac{\left\lfloor \frac{7+\sqrt{1+48t}}{2} \right\rfloor}{\left\lfloor \frac{5+\sqrt{49+96t}}{2} \right\rfloor}.$$

Let us write $48t+1 = a^2+b$, where a, b are non-negative integers such that $0 \leq b < 2a+1$. But then

$$\frac{m_g}{\kappa_{max}} \geq \frac{a+6}{5 + \sqrt{2a^2 + 4a + 47}} \geq \frac{\sqrt{2}}{2},$$

whenever $a \geq 6$.

Moreover when $1 \leq a \leq 5$, it follows that $g \leq 1$; i.e., S_g is the torus. But we already know that we can saturate the entire connectivity interval for the torus. So Case 1 is proved.

Case 2. Suppose g is even. Say $g = 2t$. Then

$$m_g = \frac{\left\lfloor \dfrac{5+\sqrt{1+48t}}{2} \right\rfloor + 1}{\left\lfloor \dfrac{5+\sqrt{1+96t}}{2} \right\rfloor}.$$

But $1 + 96t < 49 + 96t$ and so we are done by the argument for Case 1.

Now suppose $m_g \equiv 2, 5(\bmod\ 12)$.

Case 3. First suppose g is odd.

Then proceeding as in Case 1, it may be shown that

$$\frac{m_g - 1}{\kappa_{max}} = \frac{\left\lfloor \dfrac{5+\sqrt{1+48t}}{2} \right\rfloor}{\left\lfloor \dfrac{5+\sqrt{49+96t}}{2} \right\rfloor} \geq 0.7,$$

for $a \geq 66$.

When $a < 66$, it follows that $g < 2t + 1 \leq 187$. However, the number of values of g that must be checked can be reduced from 187 to just 9 by recalling that we are in the case in which $m_g \equiv 2, 5(\bmod\ 12)$. It follows easily then that the ratio $(m_g - 1)/\kappa_{max} \geq 0.7$ in eight of these cases. It remains only to consider the single case when $g = 35$.

It will suffice to construct a graph G which has $\kappa = 17$ and genus 35. But this construction may be carried out in a manner similar to that above.

Case 4. Finally, suppose g is even.

Letting $g = 2t$ and $1 + 48t = a^2 + b$ and proceeding as in Case 3, it may be shown that $m_g/\kappa_{max} \geq 0.7$ for all $a \geq 48$; i.e., for all $g \geq 95$. But there are only six values of $g \leq 94$ for which $m_g \equiv 2, 5(\bmod\ 12)$ and one easily checks each of these values directly to show that $(m_g - 1)/\kappa_{max} \geq 0.7$. This completes the proof of Case 4 and the corollary follows.

∎

The next result follows immediately from Theorem 5.4.

Corollary 5.5. For any orientable surface S_g,
(i) $\kappa_{gen}(S_g) = \kappa_{max}(S_g)$, when $0 \leq g \leq 11$,
(ii) $\kappa_{gen}(S_g) \geq \lceil (\sqrt{2}/2)\kappa_{max}(S_g) \rceil$, when $g \geq 12$ and $m_g \not\equiv 2, 5(\bmod\ 12)$, and
(iii) $\kappa_{gen}(S_g) \geq \lceil 0.7\kappa_{max}(S_g) \rceil$, when $g \geq 12$ and $m_g \equiv 2, 5(\bmod\ 12)$.

∎

6. The Non-orientable Case

The constructions in the non-orientable case parallel in spirit those of the orientable case. Therefore, here we will primarily stress the differences between the non-orientable and the orientable cases.

(1) We shall conform to the tradition of considering the six congruence classes modulo 6 for the non-orientable cases and to that end let $m = 6s + k$ where s and k are non-negative integers with $0 \leq k \leq 5$. Let $\overline{\gamma}(s, k) = \overline{\gamma}(K_{6s+k})$.

(2) For each pair of s and k, the base embedding Ψ is a triangulation of $N_{\overline{\gamma}(s,k)}$ when $k = 0, 1, 3, 4$, and $K_{6s+k} - K_2$ into $N_{\overline{\gamma}(s,k)-1}$ when $k = 2, 5$ [J1, K1, R1, R2, RY1].

(3) Let $\overline{l}_k(s) = 2[\overline{\gamma}(s, k+1) - \overline{\gamma}(s, k)] + 1$, for $k \neq 2, 5$, and $\overline{l}_k(s) = 2[\overline{\gamma}(s, k+1) - \overline{\gamma}(s, k)] + 3$, for $k = 2, 5$. This number is an upper bound of the number of crosscaps we need to construct the desired non-orientable surfaces.

(4) For $k = 2, 5$, the base embeddings are not necessarily non-orientable [R1]. In each of these cases, we need at least two tubes to construct the desired surfaces and we always twist the last tube to obtain a non-orientable surface.

(5) If a given non-orientable surface has odd Euler characteristic, when constructing embeddings in this surface we need to add a crosscap on a connecting tube to guarantee that the resulting surface is non-orientable. Also we need to put extra edges on this crosscap that are not parallel to other edges to obtain a genus embedding. The crosscap is added on the last tube for the construction analogous to Construction I and is added on the first tube for the construction analogous to Construction II.

Using arguments similar to those in the orientable cases, we obtain the following results. The proofs are omitted here, but may be checked in an Appendix available on the world wide web [PZ2].

Theorem 6.1. Suppose h is any positive integer. For each non-orientable surface N_h define the quantity m_h by $m_1 = 6$ and for $h \geq 2$ by

$$m_h = \left\lfloor \frac{5 + \sqrt{1 + 24\lfloor \frac{h}{2} \rfloor}}{2} \right\rfloor + 1.$$

Write $m_h = 6s + k$, where $0 \leq k \leq 5$. Then for all integers i in the interval $[1, m_h]$ when $k \neq 2, 5$ (respectively, in the interval $[1, m_h - 1]$ when $k = 2$ or 5), there exists a graph G with $\overline{\gamma}(G) = h$ and $\kappa(G) = i$.

∎

Theorem 6.2. For every integer $h > 0$, let m_h be defined as in Theorem 6.1. Then when $1 \leq h \leq 7$, for every integer i in $[1, \kappa_{max}(N_h)]$, and when $h \geq 8$, for every integer i in $[1, \lfloor (\sqrt{2}/2)\kappa_{max}(N_h) \rfloor]$, when $m \not\equiv 2, 5(\bmod\ 6)$ and for every integer i in $[1, \lfloor 0.7\kappa_{max}(N_h) \rfloor]$ when $m \equiv 2, 5(\bmod\ 6)$, there exists a graph G with connectivity i which genus embeds in surface N_h.

∎

Theorem 6.3. For any non-orientable surface N_h,
(i) $\kappa_{gen}(N_h) = \kappa_{max}(N_h)$, when $1 \le h \le 7$,
(ii) $\kappa_{gen}(N_h) \ge \lceil (\sqrt{2}/2)\kappa_{max}(N_h) \rceil$, when $h \ge 8$ and $m_h \not\equiv 2, 5(\bmod 6)$, and
(iii) $\kappa_{gen}(N_h) \ge \lceil 0.7\kappa_{max}(N_h) \rceil$, when $h \ge 8$ and $m_h \equiv 2, 5(\bmod 6)$.

■

7. Concluding Remarks

It has been shown above that for genus embeddings, one can always saturate a subinterval of the connectivity interval of a surface Σ, namely the subinterval $[1, \lfloor 0.7\kappa_{max}(\Sigma) \rfloor]$ (or sometimes on the subinterval $[1, \lfloor (\sqrt{2}/2)\kappa_{max}(\Sigma) \rfloor]$). But what about saturation of the remaining subinterval $[\lfloor 0.7\kappa_{max}(\Sigma) \rfloor + 1, \kappa_{gen}(\Sigma)]$?

For some surfaces (such as S_{36}), saturation is not possible because $\kappa_{gen} < \kappa_{max}$ for these surfaces. In [PZ1] these are called **Class** $\mathcal{B}$ surfaces and it is shown there that such surfaces must occur periodically infinitely often as the value of the genus goes to infinity.

In the Introduction it was claimed that a complete answer to Question 2 would imply the solution to the problem of determining the genus of the octahedron $O(m)$ for some values of m for which this problem is still currently not solved. We conclude with further explanation of this claim. (We will restrict our discussion to the orientable case.)

We recall some terminology and a few results from [PZ1]. Call surfaces for which $\kappa_{gen} = \kappa_{max}$, **Class** $\mathcal{A}$. Thus since it is clear that $\kappa_{gen} \le \kappa_{max}$ for all surfaces, the set of all surfaces partitions into those which are Class $\mathcal{A}$ and those which are Class $\mathcal{B}$. The Class $\mathcal{A}$ and Class $\mathcal{B}$ genera are nicely arranged in the following sense. Every finite interval of genera of the form $[\gamma(K_m) + 1, \gamma(K_{m+1})]$ can be written as the disjoint union of two subintervals $[\kappa(K_m) + 1, g_{\mathcal{A}} - 1] \cup [g_{\mathcal{A}}, \gamma(K_{m+1})]$ where the first of the two subintervals consists entirely of Class $\mathcal{B}$ genera and the second entirely of Class $\mathcal{A}$ genera. Moreover, it was shown that if $m \ge 30$, then the Class $\mathcal{B}$ subinterval is not empty. The value of $g_{\mathcal{A}}$ is called the **breaking point** of the interval $[\gamma(K_m) + 1, \gamma(K_{m+1})]$.

We now show that if we knew the complete answer to Question 2, then we could compute the genus of the octahedron $O(m)$ for at least some of the values of m for which it is presently unknown.

Write $m = 12s + k$ where $0 \le k \le 11$. In [PZ1] it was shown that for $k = 1, \ldots, 7$ and 11, $g_{\mathcal{A}}$ for the interval $[\gamma(K_m) + 1, \gamma(K_{m+1})]$ must equal to $\gamma(O(m+1))$. (We stress here that this does *not* mean that we know the numerical value of $\gamma(O(m + 1))$!) Set $i = \kappa(O(m + 1))$ in Question 2, where $m = 12s + k$ and assume that k has one of the eight values $1, \ldots, 7$ or 11. (Clearly $i = m - 1$.)

Inspect the set of genera $1, 2, 3, \ldots,$ in increasing order. Among the genera in the interval $[1, \gamma(K_m) - 1]$, *none* has an $(m - 1)$-connected graph which genus embeds there, since $\kappa_{gen} \le \kappa_{max} \le m - 2$ for all these genera. The genus $\gamma(K_m)$ *does* have an $(m - 1)$-connected graph which genus embeds (namely, K_m!). Then in the next subinterval $[\gamma(K_m) + 1, g_{\mathcal{A}} - 1]$, *none* of the genera admits the genus embedding of any

$(m-1)$-connected graph. That is because the genera in this subinterval all correspond to Class $\mathcal{B}$ surfaces and hence $\kappa_{gen} < \kappa_{max} = m - 1$ for these genera.

The next genus encountered is $g_{\mathcal{A}}$ and since it is the genus of a Class $\mathcal{A}$ surface, it does admit the genus embedding of an $(m-1)$-connected graph. (We do not necessarily know the identity of such a graph, but that is irrelevant for our purposes here.) So starting at genus 1 and allowing the genus to increase by one at each step, since we know the answer to Question 2 at each step, we simply record the *second* genus encountered where the answer to Question 2 is "yes"; that is, the second genus encountered which admits the genus embedding of some graph having connectivity $m - 1$ (the first genus encountered for $\kappa = m - 1$ is $\gamma(K_m)$). We know that the numerical value of this genus must be $g_{\mathcal{A}}$. Since we have assumed that $m \equiv 1, \ldots, 7(\bmod\ 12)$ or $m \equiv 11(\bmod\ 12)$, by Theorem 5.1 of [PZ1] we know that this numerical value for $g_{\mathcal{A}}$ must be the same as the value of $\gamma(O(m+1))$. In this way, we have determined the numerical value of $\gamma(O(m+1))$.

We conclude with the following conjecture:

Conjecture: For any integer $i \in [1, \kappa_{gen}(\Sigma)]$, there is a graph which genus embeds in Σ and has connectivity i.
